Notes:

[1] Each congener mix is analyzed in triplicate to establish the retention times of the PCB isomers in the absence of co-eluting isomers. The elution order listed here is used to assign peak identifications in the separate mixture analysis. The average retention time established in the analysis of the separate mixtures is then used to establish relative retention times. (See sections 10.2.3)

[2] BZ/IUPAC Number, if different.

Eurofins/TestAmerica Knoxville Specialty Organics Group GC/MS Initial Calibration Data Review Checklist
Method 1668 or SOP Number: KNOX-ID-0013 Revision 19

Mass Res Date/Time:		Inst:		2nd Source Filename:	
ADII Batch #(s):		WL #:		Job #:	

CS0.5 Filename	CS1 Filename	CS2 Filename	CS3 Filename	CS4 Filename	CS5 Filename

Review Items	N/A	Yes	No	If No, why is data reportable?	2nd √
1. Was the mass resolution documented before beginning the initial calibration?					
2. Was the instrument resolution ≥8,000 throughout (≥ 10,000 for m/z 342.9792, PFK) and ≥10,000 in the center of each m/z range for the PFK masses or FC43 masses?					
3. Were the measured exact masses listed above within 5 ppm at reduced accelerating voltage?					
4. Have PCB Mixes 1 - 5 been analyzed using the installed column to assign congener retention times, method retention times, and MID switch points?					
5. Were the calibration standard solutions, at the number and concentrations specified in the SOP, analyzed?					
6. Was date/time of analysis verified as correct?					
7. Was the valley height less than 40% of the height of the shorter of the two peaks for the pair PCB 23 and PCB 34, and the pair PCB 182 and PCB 187 in the CS3 standard?					
8. Did the PCB co-elution 156/157 co-max within 2 seconds at peak maximum on the SPB-octyl?					
9. Was the absolute retention time of PCB 209 greater than 55 minutes in the CS3 standard?					
10. Were the response factors calculated for each labeled standard and unlabeled native analyte using the SOP specified reference compound (Table 2), quantitation ions (Table 8), and formula (10.3.4.2)?					
11. Is the %RSD acceptable for all native analytes (within ± 20% calculated by IDAs, and within ± 35% when not calculated by IDAs)?					
12. Is the %RSD acceptable (within ± 35%) for all labeled standards?					
13. Are all S/N ratios ≥10 for the GC signals in each EICP (extracted ion chromatographic profile) including IDAs? (Exception: Secondary native dichloro biphenyl channel m/z 223.9974, PFK)					
14. Are the ion abundance ratios for all native Toxics/LOCs and all labeled compounds within the control limits specified? (Exception: Native dichlorobiphenyls, PFK) (Table 9)					
15. Were all toxic congeners uniquely resolved from non-toxic congeners?					
16. Was an ICV analyzed and calculated according to Section 10.3.5 of the SOP?				< 5 outliers, none more than ±50% D.	
17. If manual integrations were performed, are the analyst's name, reason and date noted in AD II?					
18. If criteria were not met, was a NCM generated?					
19. Do the ICAL AD II batches contain a completed checklist for this work list?

End Mass Res:		AD II Batches:				ICAL Event#	

Review Items	N/A	Yes	No	If No, why is data reportable?	2nd Level
1. Was the mass resolution documented at both the beginning and end of the 12 hour shift and is data verified as within the 12 hour clock?					
2. Were all graphics uploaded to AD II?					
3. Was the mass resolution scanned and attached to the corresponding WDMCCV?					
4. Was the instrument resolution ≥8,000 throughout (≥ 10,000 for m/z 342.9792) and ≥10,000 in the center of each m/z range for the PFK masses as listed in the SOP or ≥10,000 in the center of each m/z range for the FC43 masses as listed in the SOP.					
5. Were the measured exact masses listed above within 5 ppm at reduced accelerating voltage?					
6. Were the date and time of analysis verified as correct?					
7. Were the MID switch points set to encompass the retention time windows of each congener group?					
8. Was the valley height less than 40% of the height of the shorter of the two peaks for the pair PCB 23 and PCB 34, and the pair PCB 182 and PCB 187?					
9. Did the PCB co-elution 156/157 co-max within 2 sec at peak max on the SPB-octyl?					
10. Was the continuing calibration performed at the beginning of the 12 hour period after successful mass resolution and GC resolution performance check?					
11. Was the %D for all Toxic analytes within ± 30% for 1668A/B and ± 25% for 1668C? (PCB 81, 77, 123, 118, 114, 105, 126, 167, 156, 157, 169, 189) Was the %D for all LOC analytes within ± 30% for 1668A/B and ± 25% for 1668C? (PCB 1, 3, 4, 15, 19, 37, 54, 104, 155, 188, 202, 205, 206, 208, 209)					
12. Was the %D for all non-toxic/non-LOC analytes within ± 30% (for all versions of 1668)?					
13. Were the response factors calculated for each labeled standard and unlabeled target analyte using the SOP specified reference compound (Table 2), quantitation ions (Table 8), and formula (10.3.4.2)?					
14. Were the absolute retention times of all labeled IDAs within ± 15 seconds of the retention times obtained during initial calibration?					
15. Are %D within ± 50% for all labeled IDAs (for 1668A/B) or -50/+45% (for 1668C) in the calibration?					
16. Are the %D within ± 50% for all labeled field surrogates (for all versions of 1668) in the calibration?					
17. Are the %D within -40/+30% (for 1668A/B) or ± 25% (for 1668C) for all labeled surrogates in the calibration? **Note: for 1668C, PCB28L's lower limit can extend to -35%D.**					
18. Are all S/N ratios ≥10 for the GC signals in each EICP (extracted ion chromatographic profile) including internal standards?					
19. Are RRTs of all unlabled toxic/LOC analytes within their respective RRT limits?					
20. If manual integrations were performed, are they clearly identified in the AD II batch with the analyst, date and reason?					
21. If criteria were not met, was a NCM generated?					
22. Do the AD II batches contain a completed checklist for this work list?

Appendix I - SPB-Octyl Guard Column Installation and Conditioning

1. Guard column installation on SPB-Octyl

- SPB-Octyl is 30M x 0.25mm ID x 0.25 uM film thickness (Supelco # 24218-U)

- Guard column is 10M non-polar fused silica, 0.25mm ID. This can be purchased in a 60M length and cut down to 10M as needed (Supelco # 25783). The measuring/cutting process is a chore and usually requires an assistant. Supelco does not offer 0.25mm ID non polar fused silica in a 10M length. Restek also does not offer a 10M pre-cut length.

- Butt connector with ferrule – Supelco # 23796
- Butt connector ferrules – Supelco # 23797 (pack of 2)

- The attachment of the guard column to the column via the butt connector and ferrule is a bit delicate. It can be learned by reading the instructions or it can be demonstrated. Upon GC installation, the butt connector threading usually loosens up a bit. This generally should not cause the ferrule to leak, but it is a good idea to snug up the threads a couple times until the threads no longer come loose.

2. SPB-Octyl column conditioning

- As purchased, the SPB-Octyl is unsuitable for installation into an ion source. The column requires an extensive conditioning before use. Even with the conditioning, at our upper run temperature of 270°C, a new column will bleed extensively on the back end of the mass 181 tuning peak, but this bleed will decrease over time.

- To condition an SPB-Octyl column, it should be installed in a GC at ambient temperature with gas flowing to allow sufficient time (about 1 hour) for oxygen to purge from the system. It is then heated to 270°C for at least 18 hours with the column flowing into the oven to avoid trashing the source. **24 hours is preferable.** Set the GC mode to splitless, constant flow. Enter the column dimensions as follows: Length: 60m, ID=250nm, film thickness=0.250um. Flow rate should be 1.5mL/min (in an HP6890 GC, with a 10m guard column and a 30m spb-octyl, this should give a head pressure reading of ~ 47psi when the oven has reached 270 C). Check that you have flow through the column by immersing the source end into a beaker of methanol and watch for bubbles. They should come out of the source end very rapidly if you have installed everything correctly. This conditioning time will bring the SPB-Octyl column to a state where the operator can install it into a source and starting making test runs to establish the GC length configuration that will elute decachlorobiphenyl at 56:00 minutes.

STANDARD OPERATING PROCEDURE

TITLE: Extraction of Polychlorinated Biphenyl (PCB) Isomers for Analysis by Isotope Dilution HRGC/HRMS (EPA Methods 1668A, 1668B and 1668C)

1. Scope and Application

1.1 This procedure is used by Eurofins TestAmerica Knoxville for the extraction of PCB isomers from a variety of environmental matrices. This procedure is based on EPA methods 1668A, 1668B and 1668C, and is designed to meet analytical program requirements where isotope dilution HRGC/HRMS analysis of polychlorinated biphenyl (PCB) isomers is specified.

1.2 This procedure is based on "performance-based" methods. These reference methods allow modifications to overcome interferences or lower the cost of measurements if all performance criteria in the methods are met and method equivalency is established. Modifications and enhancements to the referenced methods have been incorporated into this procedure and are listed in section 17.1.

1.3 Because of the extreme toxicity of many of these compounds, the analyst must take the necessary precautions to prevent exposure to materials known or believed to contain PCBs. It is the responsibility of all laboratory personnel to ensure that safe handling procedures are employed. Section 5 of this procedure discusses safety procedures.

2. Summary of Method

2.1 Screening and protocol assignment

2.1.1 All solid, sediment, waste and tissue samples are screened by GC/ECD prior to extraction. Aqueous samples may be screened if the potential for congener levels is suspected to be above 40 ng/L. Variations to sample size, spiking levels and final volume are established based on the screening result. Refer to Table 5.

2.2 Extraction

2.2.1 Aqueous samples (samples containing less than one percent solids): Stable isotopically labeled analogs of the toxic PCBs plus additional labeled PCBs (i.e., $^{13}C_{12}$ labeled isotope dilution analytes) are typically spiked into a 1-L sample, and the sample is extracted with methylene chloride using separatory funnel techniques.

2.2.2 Solid and sediment samples: A 1.0 g sub-sample is screened to determine the greatest concentration for individual congeners. Based on the screen results, the sample is prepared by one of four protocols (refer to Table 5). Each protocol defines the sample amount to be extracted, the fraction of the extract to be used, and the final extract volume. Protocol 1 is for samples which can be processed without adjustments for high levels of PCB congeners. In this protocol, the isotope dilution analytes are spiked into a sample containing 10 g of solids. The sample is extracted for 18-24 hours with 1:1 hexane/acetone using a Soxhlet extractor. The extract is concentrated for cleanup.

NOTE: Sample sizes may be adjusted for dry weight or processed as received. The laboratory default for soil samples is to process as received. The laboratory default for sediment samples is to adjust the sample amount extracted to a minimum dry weight.

2.2.3 Multi-phase samples: Samples containing multiple phases are separated and the phases are extracted following the procedures for the appropriate matrix. The extracts may be combined for cleanup and analysis or processed separately. Specific handling of multi-phase samples should be discussed and documented with the project manager prior to extraction of samples.

2.2.4 Tissue samples: A 1.0 g sub-sample may be screened to determine the greatest concentration for individual congeners. Based on the screen results, the sample is prepared by one of four protocols (refer to Table 5). Each protocol defines the sample amount to be extracted, the fraction of the extract to be used, and the final extract volume. Protocol 1 is for samples which can be processed without adjustments for high levels of PCB congeners. In this protocol, a 10 g aliquot of homogenized tissue is blended with sodium sulfate, spiked with the isotope dilution analytes, and extracted for 18-24 hours in a Soxhlet extractor using 1:1 hexane/acetone. If required, a portion of the extract is used to determine the lipid content. (Refer to SOP KNOX-OP-0020, “Gravimetric Percent Lipids Determination” current revision.) The remaining extract is concentrated for cleanup.

2.2.5 Waste samples: Non-aqueous liquids such as oils and organic solvents are diluted or solvent exchanged in hexane.

2.2.6 Refer to SOP KNOX-OP-0010, current revision, for extraction of source air and ambient air samples.

2.3 After extraction, samples may be cleaned up using back-extraction with sulfuric acid, gel-permeation chromatography and silica gel chromatography. Cleanup surrogates are added to each extract prior to initiating any cleanup steps.

2.4 After cleanup, the extract is concentrated to the appropriate final volume (refer to Table 5). Internal standards are added to each extract and extracts are delivered to the HRMS lab for analysis. Refer to SOP KNOX-ID-0013, current revision.

3. Definitions

NOTE: Terminology differences existing in some isotope dilution reference methods regarding the functionality of the labeled analogs may lead to confusion. For example, EPA's Office of Solid Waste methods (8280, 8290) use the term "Internal Standards" to describe the labeled analogs which are added to the sample prior to extraction and used to quantitate the native targets. EPA's Office of Water methods (1613B, 1668, Revision A) use the term "Labeled Analogs" to describe these same compounds while using the term "Internal Standards" to describe the labeled analogs which are added to the extract just prior to analysis and used to quantitate the recovery of the labeled analogs added before extraction. EPA's Office of Solid Waste methods (8280, 8290) uses the term "Recovery

Standards" to describe these later labeled analogs.

The terminology listed below is used in the laboratory for all Standard Operating Procedures and internal communications.

3.1 Isotope dilution analytes (IDAs): Isotopically labeled analogs of the target analytes that are added to every sample, blank, quality control spike sample, and calibration solution. They are added to the sample before extraction and are used to calculate the concentration of the target analytes or detection limits.

3.2 Cleanup surrogates (SU): Isotopically labeled compounds that are added to samples, blanks, quality control samples, and calibration solutions. They are added to the samples after extraction but prior to extract cleanup, and are used to judge the efficiency of the cleanup procedures.

3.3 Internal standards (IS): Isotopically labeled compounds which are added to every sample, blank, and quality control spike sample extract prior to analysis. They are used to measure the recovery of the IDAs and the cleanup surrogates.

3.4 Additional definitions can be found in the Eurofins Knoxville Quality Assurance Manual.

4. Interferences

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or elevated baselines causing misinterpretation of chromatograms. Specific selection of reagents and solvents may be required. Where possible, reagents are cleaned by extraction or solvent rinse. The non-coplanar PCB congeners 105, 114, 118, 123, 156, 157, 167, and 180 have been shown to be very difficult to completely eliminate from the laboratory at the minimum levels in this method, and baking of glassware in a kiln or furnace at 450 - 500°C may be necessary to remove these and other contaminants.

4.2 Proper cleaning of glassware is extremely important because glassware may not only contaminate the samples but may also remove the analytes of interest by adsorption on the glass surface. For specific glassware cleaning procedures, see SOP KNOX-QA-0002, “Glassware Cleaning”, current revision.

4.3 All materials used in the analysis shall be demonstrated to be free from interferences by preparing laboratory method blanks (section 9.5) with each sample batch.

4.4 Interferences co-extracted from samples will vary considerably from source to source, depending on the diversity of the site being sampled. Interfering compounds may be present at concentrations several orders of magnitude higher than the PCBs. The most frequently encountered interferences are chlorinated dioxins and dibenzofurans, methoxy biphenyls, hydroxy-diphenyl ethers, benzylphenyl ethers, polynuclear aromatics and pesticides. Because very low levels of PCBs are measured by this method, the elimination of interferences is essential. The cleanup steps given in section 11.9 can be used to reduce or eliminate these interferences and

thereby permit reliable determination of the PCBs at the levels required by the method.

4.5 Cleanup of tissue - The natural lipid content of tissue can interfere in the analysis of tissue samples for PCBs. The lipid contents of different species and portions of tissue can vary widely. Lipids are soluble to varying degrees in organic solvents and may be present in sufficient quantity to overwhelm the column chromatographic cleanup procedures used for sample extracts. Lipids must be removed by the sulfuric acid cleanup procedure (section 11.9.5) followed by GPC cleanup (section 11.9.6).

5. Safety

5.1 Employees must abide by the policies and procedures in the Corporate Safety Manual, Radiation Safety Manual and this document.

5.2 Eye protection that satisfies ANSI Z87.1 (as per the Corporate Safety Manual), laboratory coat and appropriate gloves must be worn while samples, standards, solvents and reagents are being handled. Disposable gloves that have become contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.3 Latex and vinyl gloves provide no protection against most of the organic solvents used in this method. For the operations described herein, Nitrile gloves are to be worn. For operations using solvents that may splash, SilverShield® gloves are recommended. SilverShield® gloves protect against breakthrough for most of the solvents used in this procedure.

5.4 When using a scalpel, wear cut-resistant gloves and cut away from your hand.

5.5 Primary Materials Used: The following is a list of the materials used in this method which have a serious or significant hazard rating. **NOTE: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table.** A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Sulfuric Acid (1)	Corrosive, Oxidizer, Dehydrator	1 mg/m^3	This material will cause burns if comes into contact with the skin or eyes. Inhalation of vapors will cause irritation of the nasal and respiratory system.

Material	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Methylene Chloride	Carcinogen, Irritant	25 ppm-TWA, 125 ppm-STEL	Causes irritation to respiratory tract. Has a strong narcotic effect with symptoms of mental confusion, light-headedness, fatigue, nausea, vomiting and headache. Causes irritation, redness and pain to the skin and eyes. Prolonged contact can cause burns. Liquid degreases the skin. May be absorbed through skin.
Hexane	Flammable, Irritant	500 ppm-TWA	Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Vapors may cause irritation to the skin and eyes.
Methanol	Flammable, Poison, Irritant	200 ppm-TWA	A slight irritant to the mucous membranes. Toxic effects exerted upon nervous system, particularly the optic nerve. Symptoms of overexposure may include headache, drowsiness and dizziness. Methyl alcohol is a defatting agent and may cause skin to become dry and cracked. Skin absorption can occur; symptoms may parallel inhalation exposure. Irritant to the eyes.
Toluene	Flammable, Poison, Irritant	200 ppm-TWA, 300 ppm-Ceiling	Inhalation may cause irritation of the upper respiratory tract. Symptoms of overexposure may include fatigue, confusion, headache, dizziness and drowsiness. Peculiar skin sensations (e. g. pins and needles) or numbness may be produced. Causes severe eye and skin irritation with redness and pain. May be absorbed through the skin.
Acetone	Flammable	1000 ppm-TWA	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Nonane	Flammable	None established	Harmful if inhaled/swallowed. Vapor/mist is irritating to eyes, mucous membranes and upper respiratory tract. Causes skin irritation.
Benzene	Flammable, Toxic, Carcinogen	PEL: 1 ppm TWA ; 5 ppm, 15 min. STEL	Causes skin irritation. Toxic if absorbed through skin. Causes severe eye irritation. Toxic if inhaled. Vapor or mist causes irritation to mucous membranes and upper respiratory tract. Exposure can cause narcotic effect. Inhalation at high concentrations may have an initial stimulatory effect on the central nervous system characterized by exhilaration, nervous excitation and/or giddiness, depression, drowsiness or fatigue. Victim may experience tightness in the chest, breathlessness, and loss of consciousness.
1 – Always add acid to water to prevent violent reactions. 2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.6 Chemicals that have been classified as **carcinogens**, **potential carcinogens**, or **mutagens include** benzene, methylene chloride, polychlorinated biphenyls, and toluene. The toxicity or carcinogenicity of each reagent used in this method is not precisely defined; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be kept to a minimum.

5.7 Chemicals known to be **flammable** include acetone, benzene, hexane, nonane, and toluene.

5.8 The following material is known to be **corrosive**: Sulfuric acid.

5.9 Exposure to chemicals will be maintained as low as reasonably achievable; therefore, unless they are known to be non-hazardous, all samples will be opened, transferred and prepared in a fume hood or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.10 All procedures that involve solvents such as acetone, toluene, methylene chloride and hexane (e.g., glassware cleaning and the preparation of standards and reagents) must be conducted in a fume hood with the sash closed as far as the operations permit.

5.11 All work must be stopped in the event of a known or potential compromise to the health or safety of laboratory personnel. The situation must be reported immediately to a laboratory supervisor.

6. Equipment and Supplies

NOTE: All glassware used in extraction and cleanup procedures is pre-cleaned as described in SOP KNOX-QA-0002, “Glassware Cleaning”, current revision. When extracting PCB samples, all of the reusable glassware used in the extraction and concentration process is identified with a "P" (for aqueous sample glassware), “L” or “LL” (for solid sample glassware) etched mark. All glassware used must be low level glassware.

6.1 Miscellaneous Laboratory Equipment

6.1.1 Laboratory fume hood of sufficient size to contain the equipment used for sample preparation

6.1.2 Oven, capable of maintaining a temperature of 125 to 135°C

6.1.3 Balance, >100 g capacity, accurate to $\pm$ 0.01 g

6.1.4 Balance, >2000 g capacity, accurate to $\pm$ 0.1 g

6.1.5 Syringes, various sizes

6.1.6 Borosilicate 5.75 inch and 9.0 inch disposable pipettes with latex bulbs

6.1.7 Glass pipets, 1 mL, Class A

6.1.8 Graduated cylinders, 100 mL and 1000 mL capacity

6.1.9 PTFE squirt bottles, 500 mL

6.1.10 250 mL and 500 mL flasks

6.1.11 Ultra-Pure PTFE boiling stones

6.1.12 Glass wool, solvent rinsed

6.2 Tissue Homogenization Equipment:

6.2.1 Laboratory blender with glass body and stainless steel blades

6.2.2 Industrial meat grinder, Intedge Industries, Model C2H, or equivalent

6.2.3 Laboratory homogenizer, OMNI GLH-01, Model LR060902, or equivalent

6.2.4 Scalpels or knives

6.2.5 Cut-resistant gloves

6.3 Aqueous Sample Extraction Equipment

6.3.1 Separatory funnels, 250, 500, and 2000 mL, with PTFE stopcocks

6.3.2 Separatory funnel rotator

6.4 Solid/Tissue Sample Extraction Equipment

6.4.1 Soxhlet extractors, 50-mm ID, 200-mL capacity with 500 mL flasks

6.4.2 Glass condensers, capable of fitting top of Soxhlet apparatus

6.4.3 Whatman high purity glass fiber extraction thimbles

6.4.4 Heating mantles with temperature control

6.4.5 Flasks, Erlenmeyer, 500 mL

6.4.6 Beakers, 500 mL

6.4.7 Spatulas, stainless steel

6.5 Filtration Equipment

6.5.1 Glass or stainless steel funnels

6.5.2 Phase separation paper, Glass fiber filters

6.5.3 Buchner funnel, 15 cm

6.5.4 Glass-fiber filters for Buchner funnel

6.5.5 Filtration flasks, 1.5 to 2.0 L, with side arm

6.6 Cleanup Equipment

6.6.1 Disposable pipets, 150 mm long x 5 mm ID

6.6.2 Disposable pipets, 230 mm long x 5 mm ID

6.6.3 20 mm x 240 mm glass columns with support ring and tapered tip, for silica gel cleanup

6.6.4 Vortex mixer

6.6.5 Gel Permeation chromatography system

6.7 Concentration Equipment

6.7.1 Nitrogen blowdown apparatus, N-EVAP (Organomation Associates, Inc., South Berlin, MA), installed in a fume hood

6.7.2 Kuderna-Danish (KD) Apparatus - 500 mL

6.7.3 Concentrator Tube, 10 mL, attached to KD with clips

6.7.4 Snyder Column, three-ball macro

6.7.5 Water Bath, heated, with concentric ring cover, capable of temperature control (± 5°C) up to 95°C. The bath must be used in a hood or with a solvent recovery system.

6.7.6 Heating mantles with temperature control

6.8 Sample Vials

6.8.1 Borosilicate glass, 12 mL and 40 mL disposable with PTFE caps

6.8.2 Mini-vials, 1.1 mL capacity with a tapered bottom, with PTFE, rubber septa and screw caps

6.8.3 Amber glass vials with PTFE-lined screw caps

6.9 Screening Equipment

6.9.1 Shaker table

6.9.2 An analytical system complete with a gas chromatograph and a ^{63}Ni electron capture detector and a data system capable of measuring peak height.

7. Reagents and Standards

CAUTION: Refer to Safety Data Sheets (SDS) for specific safety information on chemicals and reagents prior to use or as needed

CAUTION: During preparation of reagents, associates shall wear a lab coat, gloves, safety glasses with side shields, and laboratory approved shoes as a minimum. Reagents shall be prepared in a fume hood.

7.1 Pre-cleaned glass wool - Pre-clean the glass wool with methylene chloride in a Soxhlet extractor for a minimum of 4 hours.

7.2 Sulfuric acid, concentrated, reagent grade (specific gravity 1.84)

7.3 Sodium chloride, reagent grade - Prepare a 5% (w/v) solution in reagent water.

7.4 Sodium sulfate, reagent grade, anhydrous, J.T Baker 3375, or equivalent

7.4.1 Sodium sulfate may be cleaned by putting approximately 600 g of sodium sulfate in large amber-colored glass jars and completely covering with

methylene chloride and letting the sodium sulfate soak for 5 minutes. The methylene chloride is drained and this step is repeated. After the methylene chloride is drained, the sodium sulfate is transferred to a Buchner funnel fitted onto a vacuum flask and rinsed 2 times with methylene chloride while a vacuum is being applied. The sodium sulfate is then placed into shallow borosilicate glass dishes where it is allowed to dry. It is placed in an oven at 125-130°C for 1 hour to complete the drying process. After drying, the sodium sulfate is transferred into pre-cleaned glass jars with PTFE lined screw caps.

7.5 Purified nitrogen

7.6 Solvents - Acetone, toluene, n-hexane, methanol, methylene chloride, benzene and nonane; pesticide quality

7.7 Reagent water must be produced by a Millipore DI system, or equivalent, that is capable of producing water with ≥18 megohm-cm (MΩ-cm) resistivity. Reagent water must be free of the analytes of interest as demonstrated through the analysis of method blanks.

7.8 Silica gel, S679-212, Fisher Chromatographic Silica Gel, 100-200 mesh or equivalent - Prepare by Soxhlet extraction with methylene chloride for at least 6 hours. Transfer to a shallow, borosilicate glass dish and air dry. After drying, cover with aluminum foil and activate in an oven at 125-135°C for a minimum of 4 hours. Store in labeled glass jars in a desiccator until use.

7.9 3.3% Deactivated silica gel – To prepare, add 6.6 mL of reagent water to 200 g of pre-cleaned silica gel (section 7.8) in a 500 mL amber glass jar with a PTFE lined screw cap. Mix thoroughly by shaking until no lumps are visible, and the silica gel is free flowing and no longer sticks to the side of the jar. The Tornado II portable paint shaker may be used to aid in mixing these reagents. Store in a desiccator. Shake well again before each use.

7.10 Acidic silica gel – To prepare, add 57 mL of concentrated sulfuric acid to 180 g of pre-cleaned silica gel (section 7.8) in a 500 mL amber glass jar with a PTFE lined screw cap. Mix thoroughly by shaking until no lumps are visible and the silica gel is free flowing and no longer sticks to the side of the jar. The Tornado II portable paint shaker may be used to aid in mixing these reagents. Store in a desiccator. Shake well again before each use.

7.11 8082 Surrogate Mix: A surrogate spiking solution which contains 0.2 mg/L tetrachloro-m-xylene and decachlorobiphenyl. This mix is spiked into samples that are being prepared for PCB screening.

7.12 $^{13}C_{12}$ Labeled PCB Congener Standards: Obtained from Cambridge Isotope Laboratories (CIL, Andover Massachusetts) and Wellington Laboratories (Guelph, Ontario, Canada). Refer to Tables 2 and 3 for a list of individual standards. If the chemical purity is 98% or greater, the weight may be used without correction to compute the concentration of the standard. Once a standard ampoule has been

vortexed and opened, the solution is transferred to an amber glass vial with a PTFE lined screw cap. When not being used, standards are stored in the dark in a refrigerator. These purchased individual standards are used to prepare the following mixed stock solutions and spiking solutions:

7.12.1 Isotope Dilution Analyte (IDA) Stock Solution: Prepared by adding 0.625 mL of the 40,000 ng/mL $^{13}C_{12}$ PCB 170 standard to 25 mL of the 1000 ng/mL 1668 $^{13}C_{12}$ PCB mix from Cambridge Isotope Laboratories. Refer to Table 2. The concentration is verified by GC/MS before use.

NOTE: Blow down the 625 µL of PCB 170 to approximately 150-200 µL on NEVAP before adding to the 25 mL volumetric flask.

7.12.2 IDA Spiking Solutions: They are prepared by diluting the 1000 ng/mL IDA stock solution to a concentration of 10 ng/mL in acetone in a 200 mL volumetric. 0.200 to 4.0 mL of the 10 ng/mL solution is added to each sample prior to extraction. 0.200 mL is added to each aqueous sample extract. Refer to Table 5, "Assignment of Sample Preparation Protocols" to determine the exact volume to add to solid samples.

7.12.3 Internal standard Stock Solution: Cambridge Part# EC-5595 labeled internal standards listed in Table 3 at a concentration of 1000 ng/mL in nonane. The concentration is verified by GC/MS before use.

7.12.4 Internal standard Spiking Solution: Prepared by diluting the 1000 ng/mL internal standard stock solution to a concentration of 100 ng/mL in nonane in a 25 mL volumetric. 100 µL of this spiking solution is added to each solid, tissue or waste sample extract prior to analysis, whereas, 20 µL is added to each aqueous sample extract.

7.12.5 Cleanup Surrogate Stock Solution: Cambridge Part# EC-4978-5X labeled cleanup surrogates listed in Table 3, at a concentration of 5000 ng/mL in nonane. The concentration is verified by GC/MS before use.

7.12.6 Cleanup Surrogate Spiking Solution: Prepared by diluting the 5000 ng/mL cleanup surrogate stock solution to a concentration of 10 ng/mL in hexane. 0.5 mL or 1.0 mL of this solution is added to each solid/tissue sample extract prior to cleanup (refer to Table 5), whereas, 0.20 mL is added to each aqueous sample extract.

7.12.7 Field Surrogate Stock Solution: Prepare by adding 0.3 mL of ($^{13}C_{12}$ PCB 95) 50,000 ng/mL of Wellington MBP-95 to 3.0 mL of 5000 ng/mL Cambridge EC-5596 to a concentration of 5000 ng/mL in nonane.

7.12.8 Field Surrogate Spiking Solution: Prepare by diluting 5000 ng/mL stock solution to a concentration of 10 ng/mL in hexane.

7.13 Target Analyte PCB Congener Standard Mix - Obtained as a Certified Reference Standard from Accustandard (New Haven, CT). This standard contains all 209 PCB congeners at 4000 ng/mL in nonane. If the chemical purity is 98% or greater, the

weight may be used without correction to compute the concentration of the standard. Once a standard ampoule has been vortexed and opened, the solution is transferred to an amber glass vial with a PTFE-lined screw cap. When not being used, the standard is stored in the dark in a refrigerator at 4 ± 2°C. This purchased standard is used to prepare the LCS spiking solution:

7.13.1 LCS Spiking Solutions: They are prepared by diluting the 4000 ng/mL target analyte PCB congener standard to a concentration of 5.0 ng/mL in acetone. The concentration is verified by GC/MS before use. 1.0 mL of the 5.0 ng/mL solution is added to each solid LCS prior to extraction, whereas 0.200 mL is added to each aqueous LCS prior to extraction.

7.14 QC Check Sample: A QC Check Sample should be obtained from a source independent of the calibration standards. This check sample is a certified standard reference material (SRM) containing the PCBs in known concentrations in a sample matrix similar to the matrix under test.

8. Sample Collection, Preservation and Storage

8.1 Sampling is not performed for this method by Eurofins TestAmerica Knoxville. For information regarding sample shipping, refer to SOP KNOX-SC-0003, "Sample Receipt and Login", current revision.

8.2 Sample Storage

8.2.1 Store aqueous samples in the dark at ≥0°C to ≤6°C.

8.2.2 Store solid and tissue samples in the dark at ≤-10°C.

8.3 Holding Times

8.3.1 If stored according to the conditions specified in section 8.2, samples may be stored for up to one year.

8.3.2 Store sample extracts in the dark at room temperature until analyzed. If stored in the dark at room temperature, sample extracts may be stored for up to one year.

9. Quality Control

9.1 An initial demonstration of capability (IDOC) is performed to demonstrate the ability to generate acceptable precision and accuracy.

9.1.1 Extract, cleanup, concentrate, and analyze four 1-L aliquots of reagent water (for aqueous samples) or four aliquots of sodium sulfate (for solid/tissue samples) spiked with IDAs, cleanup surrogates, internal standards and the LCS target analyte spiking solution, according to the procedures in section 11. All sample processing steps that are to be used for processing samples, including preparation, extraction and cleanup, shall be included in this test.

9.1.2 Using the results of the set of four analyses, compute the average percent recovery (%R) of the extracts and the relative standard deviation (RSD) of the concentration in ng/mL for each compound.

9.1.3 For each PCB and labeled compound listed in Table 4, compare the RSD and %R with the corresponding limits for initial precision and recovery. If the RSD and %R for all compounds meet the acceptance criteria, system performance is acceptable and analysis of samples may begin. If, however, any individual RSD exceeds the precision limit or any individual %R falls outside the range for accuracy, system performance is unacceptable for that compound. Correct the problem and repeat the test.

9.2 Isotope Dilution Analytes (IDAs): Every sample, blank, and QC sample is spiked with $^{13}C_{12}$ labeled IDAs prior to extraction. IDAs in samples, blanks, and QC samples are used to calculate the concentration of the target analytes or detection limits.

9.3 Cleanup Surrogates: Every sample, blank, and QC sample extract is spiked with $^{13}C_{12}$ labeled cleanup surrogates after extraction but prior to extract cleanup. They are used to assess the efficiency of the cleanup procedures.

9.4 Internal standards: Every sample, blank, and QC sample extract is spiked with $^{13}C_{12}$ labeled internal standards prior to analysis. They are used to measure the recovery of the IDAs and the cleanup surrogates.

9.5 Method Blank: A laboratory method blank must be run along with each batch of 20 or fewer samples. The method blank is processed in the same manner and at the same time as the associated samples. The method blank is used to identify any background interference or contamination of the analytical system that may lead to the reporting of elevated concentration levels or false positive data. Refer to the table below for a cross-reference between the sample matrix and method blank matrix.

Sample Matrix	**Method Blank Matrix**
Aqueous	Reagent water
Solid	Sodium sulfate
Tissue	Sodium sulfate
Waste	Hexane

9.6 Laboratory Control Sample: A laboratory control sample (LCS) is prepared and analyzed with every batch of 20 or fewer samples. The LCS extract must be subject to the same cleanup procedures as the associated sample extracts. LCS spike components and concentrations are listed in Table 1. Refer to the table below for a cross-reference between the sample matrix and LCS matrix

Sample Matrix	**LCS Matrix**
Aqueous	Reagent water

Solid	Sodium sulfate
Tissue	Sodium sulfate
Waste	Hexane

9.7 QC Check Sample: Analyze the QC Check Sample (section7.14) periodically to assure the accuracy of calibration standards and the overall reliability of the analytical process. It is suggested that the QC Check Sample be analyzed at least annually.

9.8 Quality Control Batch: The batch is a set of up to 20 client samples that are of the same matrix and are processed together using the same procedures and reagents. The batch must contain a method blank and a laboratory control sample.

10. Calibration and Standardization

10.1 Not applicable.

11. Procedure

11.1 One time procedural variations are allowed only if deemed necessary in the professional judgment of supervision to accommodate variations in sample matrix, radioactivity, chemistry, sample size, or other parameters. Any variations in the procedure, except those specified by project specific instructions, shall be completely documented using a Nonconformance Memo and approved by a Technical Specialist, Project Manager, and QA Manager. If contractually required, the client shall be notified.

11.2 Any unauthorized deviations from this procedure must also be documented as a nonconformance, with a cause and corrective action described.

11.3 Samples are extracted by the following procedures depending upon sample matrix. Water samples are prepared by separatory funnel liquid/liquid extraction. Solid samples including soils, sediments, tissues and solid waste materials are prepared by Soxhlet extraction. Non-aqueous liquid wastes and organic solvents are prepared by waste dilution techniques.

NOTE: Samples should be removed from the refrigerator several hours before extraction and allowed to come to room temperature before measuring the volume or performing the extraction.

11.4 Aqueous Samples (samples containing 1% solids or less)

11.4.1 Remove samples from the refrigerator and allow them to come to room temperature before measuring the volume or performing the extraction. Inspect the samples carefully for biphasic sample characteristics. If this condition exists, document the observation and contact the project manager for instructions before proceeding with the extraction.

11.4.2 For aqueous samples that potentially contain >1% visible solids (as determined visually by an experienced analyst), a percent solid determination must be performed using the following procedure.

11.4.2.1 Add 10 mL of the well shaken sample to a tared aluminum weighing dish. Weigh the dish to three significant figures. Dry the dish overnight in an oven at 105 °C. Reweigh the dish and calculate the percent solids using the following equation.

$$\%\ Solids = \frac{\text{weight of dish + sample after } d\text{rying} - \text{weight of dish}}{\text{weight of dish + sample before } d\text{rying} - \text{weight of dish}} \times 100$$

11.4.3 For samples with > 1% visible solids, consult the project manager for further instructions before proceeding with extraction using one of the options listed below:

11.4.3.1 Samples can be filtered, extracted separately as solid and aqueous fractions, and analyzed separately.

11.4.3.2 Samples can be filtered, extracted separately as solid and aqueous fractions, and the extracts combined for a single analysis.

11.4.3.3 The client may decide to resample if they determine that solids should not have been present.

11.4.4 Aqueous samples that are suspected to have congener levels above 40 ng/L may be screened before extraction to prevent instrument saturation or contamination.

11.4.4.1 Carefully shake the sample bottle well. Measure out 20 mL of water and place in a 40 mL vial.

11.4.4.2 Add 100 µL of the 0.2 mg/L 8082 surrogate mix to the 20 mL of water. (Refer to section 7.11.)

11.4.4.3 Add 20 mL of methylene chloride and shake the 40 mL vial for 2 minutes. Vent the vial several times during the 2 minutes to relieve any pressure that might have built up.

11.4.4.4 Allow the water layer and the methylene chloride layer to separate, swirling the vial gently to aid in separation of the layers.

11.4.4.5 Using a disposable pipet, pull the methylene chloride (bottom layer) out and filter it through a sodium sulfate funnel and into a clean 40 mL vial.

11.4.4.6 Concentrate the extract to approximately 100 µL. Bring the extract back up to 1 mL with hexane and deliver to the GC

group for screening. Refer to section 11.5.9 to 11.5.11 for details re. screening.

11.4.4.7 Refer to Knoxville SOP KNOX-QA-0002, current revision, for information on glassware cleaning procedures for extraction glassware.

11.4.4.8 For water samples, only use the glassware designated for water samples.

11.4.4.9 Place separatory funnels, one for each sample, in the separatory rotator set up in the hood.

11.4.4.10 Place a 500 mL flask directly beneath the separatory funnel.

11.4.4.11 Plug a glass funnel with glass wool and pour in some sodium sulfate (about 1 to 2 inches from the top). Rinse the sodium sulfate with methylene chloride. After the methylene chloride stops dripping, place the funnel on top of the flask that is fitted with a paper clip to aid in filtering.

11.4.4.12 Inspect the sample for solids or biphasic sample characteristics. If either condition exists, consult the project manager for further instructions.

11.4.4.13 Weigh the sample container on a balance (± 1 g); tare the sample and container. Transfer the sample to the extractor. Rinse the sample bottle with approximately 60 mL methylene chloride and transfer to the extractor. Reweigh the container. Assume a density of 1 g/mL and record the difference as the sample volume in TALS.

11.4.4.14 For brackish water or salt water, weigh 1.0 mL of the sample. If the weight is <0.98 or >1.02, adjust the sample volume based on the sample density.

11.4.5 For the method blank and the LCS (and LCSD, if required), use a 1000 mL graduated cylinder to measure 1000 mL of reagent water.

11.4.5.1 After placing the samples into separatory funnels including the method blank and the LCS the initial pH is measured with 0-14 wide range pH paper. Concentrated sulfuric acid is then carefully and slowly added in small increments, usually 1 to 2 mL at a time. Swirl the seperatory funnel to mix the sulfuric acid into the sample. The pH is then measured again and more sulfuric acid is added until the desired pH between 1 and 3 is achieved.

NOTE: Alternatively, the pH may be adjusted in the sample bottle prior to placing into the seperatory funnel.

11.4.6 Add 0.2 mL of the 10.0 ng/mL IDA spiking solution to each sample, method blank and LCS (see section 7.12.2). Additionally, add 0.2 mL of the 5.0 ng/mL LCS spiking solution to the LCS (and LCSD, MS/MSD, if required, see section 7.13.1). Record the amount of spike used and the spike standard number in TALS.

NOTE: Verify that each spiking solution has not expired.

NOTE: Each time the samples are spiked, the spiking process should be witnessed by another analyst. Refer to Appendix I for the steps that must be taken.

11.4.7 Add 60 mL of methylene chloride to the sample bottle and shake. Then add the methylene chloride to the separatory funnel. Add 60 mL of methylene chloride to the method blank, LCS (and LCSD, if required).

11.4.8 Secure the separatory funnel with the rotator retaining straps and rotate for 2 minutes.

CAUTION: Care should be used while performing this operation. Vent the separatory funnel frequently. Goggles may be worn when performing this procedure. Also, place a clean rag over the tip of the separatory funnel to catch any spray that might have vented.

11.4.9 Allow the water and the methylene chloride to separate. If it is not separated after 10 minutes, try to break up the emulsion by gently swirling the sample or tilting the separatory funnel on its side.

11.4.10 Drain the methylene chloride from the separatory funnel into the sodium sulfate funnel, allowing the extract to drip into the flask. Be careful not to allow water to escape the separatory funnel or the sodium sulfate will harden and block the flow of the extract. NOTE: If at least 10 minutes has elapsed and other ways of breaking up or reducing the size of the emulsion have failed, the following steps may be tried to reduce the impact of the emulsion on the sodium sulfate.

11.4.10.1 Place a large piece of pre-cleaned glass wool in the funnel containing the sodium sulfate.

11.4.10.2 Spread the glass wool out, covering the entire surface of the sodium sulfate to a depth of ~5 to 10 mm. If the emulsion is hard to break up and persistent, a small, additional layer of sodium sulfate may be added on top of the glass wool.

11.4.10.3 Drain the solvent and emulsion layer into the funnel, being careful to drain no more than 60 mL of volume if a clear phase layer cannot be determined. Record the formation of an emulsion in TALS.

11.4.10.4 If this procedure is used, the funnel should be rinsed immediately with an extra 30 mL of methylene chloride to ensure all analytes are rinsed into flask.

11.4.11 Repeat the extraction process two more times with fresh 60 mL portions of methylene chloride.

11.4.12 After the third methylene chloride portion has filtered through the sodium sulfate, rinse the funnel with approximately 40 mL of methylene chloride.

11.4.13 Remove the separatory funnel from the hood and pour the extracted water into the extracted waters waste container.

11.4.14 Remove the glass funnel from the top of the flask.

11.4.15 Add a few boiling stones to the 500 mL boiling flask. Place a 3-ball Snyder column on the boiling flask. For extracts that will go through GPC cleanup, first concentrate to approximately 20 mL methylene chloride. If GPC cleanup is not going to be performed immediately, solvent exchange the extracts to hexane as follows: Concentrate the extract to approximately 20mL, then add approximately 60 mL of hexane and concentrate to > 20 mL.

NOTE: Over-concentration of heated extracts is known to cause the more volatile PCB congeners to vaporize and be lost. Therefore, do not concentrate to less than 20 mL.

CAUTION: When extracting or concentrating a sample with hexane, toluene or any mixture containing these solvents, the analyst **must** add the boiling chips within 5 minutes of placing the flask on the heat source in order to prevent bumping of the solvent.

11.4.16 Transfer the extract into a solvent-rinsed 40 mL vial, rinsing the 500 mL flask three times with approximately 3 mL of the appropriate solvent (hexane or methylene chloride). Add the rinses to the 40 mL vial.

11.4.17 For extracts that will go through GPC cleanup, reduce the volume to approximately 6 mL methylene chloride on the N-EVAP concentration device. Proceed to section 11.9.6.

11.4.18 For extracts that will not go through GPC, reduce the volume to approximately 0.5 mL hexane on the N-EVAP concentration device. Do not allow the sample to go to dryness at any time. If an additional solvent exchange is needed, add 5 mL of hexane and swirl the vial. Reduce the volume of hexane to approximately 0.5 mL again to complete the solvent exchange. Adjust the final volume of the extract with hexane to 12 mL for acid cleanup or to approximately 4 to 6 mL for column cleanup. If the sample exhibits poor solubility in hexane, add approximately 1 mL of benzene to aid in dissolving the sample. Proceed to section 11.9.8.

11.5 Solid/Tissue Sample Screening and Assignment of Sample Preparation Protocols

11.5.1 Because of the sensitivity of method 1668, it is necessary to screen all solid samples and non-aqueous liquids before extraction to prevent instrument saturation and/or contamination.

11.5.2 Mix the sample well, take a 1.0 ± 0.1g aliquot of the sample material. Mix with sodium sulfate in an aluminum pan until the mixture is free flowing.

11.5.3 Transfer to a 40 mL vial and add 1.0 mL of the 0.2 mg/L 8082 surrogate mix. (Refer to section 7.11.)

11.5.4 Add 9 mL of hexane.

11.5.5 Cap tightly and secure on a platform shaker table.

11.5.6 Shake for 1 hour, minimum.

11.5.7 Transfer ~ 4 mL of extract into a fresh 12 mL vial, add ~2 mL of sulfuric acid; cap tightly, and shake the vial for 30 to 60 seconds. If necessary, centrifuge the extract.

11.5.8 Deliver the extract to the GC group for screening.

11.5.9 Perform a single point initial calibration for each sequence on the screening instrument.

11.5.10 If no pattern and no prominent peaks are present, process the sample using protocol 1.

11.5.11 If an Aroclor-like pattern is observed, calculate the estimated concentration of the largest peak expected in the determinative analysis, and assign an extraction protocol using the “PCB Protocol Selection” spreadsheet on the local area network in the MSOffice\template\org prep.

11.5.11.1 Determine the concentration of the most prominent technical mixture by comparison to Aroclor standards. Enter the Aroclor sample concentration (ppb) into the spreadsheet. Circle the amount entered on the GC hardcopy result.

11.5.11.2 For sediment samples, import the sample % moisture results.

11.5.11.3 Enter the average or selected surrogate recovery in the spreadsheet. The software will correct the PCB concentration for surrogate recovery.

11.5.11.4 The software will multiply the PCB concentration by 0.1 (the spreadsheet default) to correct for the weight percent of the largest single congener in an Aroclor mix. This value may be changed to represent special cases such as altered patterns or

unusual technical mixtures, but documentation of the rationale must accompany the spreadsheet.

11.5.11.5 The software will then multiply the PCB concentration by 4 to account for single-peak coelutions.

11.5.11.6 The resulting concentration is used as the estimate of the largest peak expected in the determinative analysis and to assign an extraction protocol for each sample.

11.5.11.7 An independent analyst should review the data entry and protocol assignments. Initial and date the spreadsheet. Attach the spreadsheet and supporting GC data to the extraction benchsheet.

11.5.11.8 During sample preparation, adjust the sample extraction amount, spiking volumes and final volume to reflect the selected protocol. Refer to Table 5.

11.6 Sample Pretreatment for Tissue Samples

11.6.1 If the sample matrix is tissue and has not been homogenized prior to sample receipt, the entire sample is homogenized prior to extraction using an industrial meat grinder, a laboratory blender, or a laboratory homogenizer. Select the equipment that is most appropriate for the size and type of tissue received.

11.7 Solid/Tissue Sample Soxhlet Extraction (samples containing more than 1% solids)

11.7.1 This section uses protocol 1 as an example. If another protocol has been assigned, the sample amount extracted, spike volumes and percent of extract used is modified based on Table 5.

11.7.2 Prepare and label the required number of Soxhlet systems. Refer to SOP KNOX-QA-0002, current revision, for information on cleaning procedures for extraction glassware. Visually inspect all glassware prior to use for scratches or cracks. Retire, repair or replace any glassware found to be damaged.

11.7.3 For soil samples, transfer a well-mixed 10 g aliquot (± 0.5 g) of the sample into a beaker or extraction thimble. Mix thoroughly with 20 g of sodium sulfate. Record the sample weight in TALS.

11.7.4 For sediment samples, adjust the amount weighed to achieve 10 to 10.5 g dry weight. Determine the amount of sediment sample to extract using the "Sediment Extraction Amounts" spreadsheet on the local area network in the MSOffice\template\Knx OrgPrep directory. Transfer a well-mixed aliquot of the sample into a beaker or extraction thimble. Mix thoroughly with 20 g of sodium sulfate. Record the sample weight in TALS

11.7.5 For tissue samples, weigh out 10 g (± 0.5 g) of homogenized tissue into a beaker or extraction thimble. Mix thoroughly with 20 g of sodium sulfate. Record the sample weight in TALS.

NOTE: If gravimetric lipids are to be determined using the tissue extracts, split the extract prior to the initiation of any cleanup steps and use 1 mL of the 10 mL extract for lipids determination. Refer to SOP KNOX-OP-0020, "Gravimetric Percent Lipids Determination", current revision.

11.7.6 Refer to the Section 9.5 for a cross-reference between the sample matrix and method blank matrix and Section 9.6 for the LCS matrix.

11.7.7 Spike each sample with 1.0 mL of the 10 ng/mL IDA spiking solution (see section 7.12.2).

11.7.8 Spike the LCS (and LCSD, MS/MSD, if required) with 1.0 mL of the 5.0 ng/mL LCS spiking solution (see section 7.13.1).

NOTE: Verify that each spiking solution has not expired. Record the amount and ID of each spiking reagent used in TALS.

NOTE: Each time the samples are spiked, the spiking process should be witnessed by another analyst. Refer to Appendix I for the steps that must be taken.

11.7.9 If needed, add a small amount of glass wool to the top of the extraction thimble.

11.7.10 Pour approximately 350 mL of the 1:1 hexane/acetone into a 500 mL flask. Place the flask in the heating mantle. Add several PTFE boiling stones.

CAUTION: When extracting or concentrating a sample with hexane, toluene or any mixture containing these solvents, the analyst **must** add the boiling chips within 5 minutes of placing the flask on the heat source in order to prevent bumping of the solvent.

11.7.11 Place the extraction thimble in the glass Soxhlet extractor.

11.7.12 Assemble the Soxhlet system and secure to the lab supports.

11.7.13 Adjust the temperature of the heating mantle to bring the solvent in the flask to a rolling boil. There should be a steady drip from the condensers so that the solvent should completely cycle at least 5 times an hour.

11.7.14 Soxhlet extract the sample in the above manner for 18-24 hours.

11.7.15 Turn off the heating mantle and allow the Soxhlet apparatus to cool.

11.7.16 Remove the condensers and allow the Soxhlet extractor chamber to empty; then remove the Soxhlet extractor from the 500 mL flask.

NOTE: If the samples appear to have a water layer or moisture, dry the extract by filtering it through a sodium sulfate filled funnel.

11.7.17 Add several PTFE boiling stones and place a solvent-rinsed 3-ball Snyder column on the 500 mL flask. Concentrate the extract to > 20 mL. Add 60 mL of hexane to the 500 mL flask and concentrate again to > 20 mL to remove any acetone that may still be present.

NOTE: Over-concentration of heated extracts is known to cause the more volatile PCB congeners to vaporize and be lost. Therefore, do not concentrate to less than 20 mL.

CAUTION: When extracting or concentrating a sample with hexane, toluene or any mixture containing these solvents, the analyst **must** add the boiling chips within 5 minutes of placing the flask on the heat source in order to prevent bumping of the solvent.

11.7.18 Transfer the extract into a solvent-rinsed 40 mL vial, rinsing the 500 mL flask three times with approximately 3 mL of hexane. Add the rinses to the 40 mL vial.

11.7.19 Place the 40 mL vial into the N-EVAP concentration device and reduce the volume to approximately 12 mL. Proceed to section 11.9.5 to perform acid cleanup.

11.8 Waste Sample Extraction

11.8.1 Organic wastes, oil, solids and non-aqueous sludge samples that will dissolve in solvent may be prepared by the waste dilution technique.

11.8.2 Add an appropriate amount of sample (based on screen results) to a solvent-rinsed 40 mL vial.

11.8.3 2 mL of hexane is used for the blank and LCS.

11.8.4 Spike each sample with 1.0 mL of the 10 ng/mL IDA spiking solution (see section 7.12.2).

11.8.5 Spike the LCS (and LCSD, MS/MSD, if required) with 1.0 mL of the 5.0 ng/mL LCS spiking solution (see section 7.1

NOTE: Verify that each spiking solution has not expired.

NOTE: Each time the samples are spiked, the spiking process should be witnessed by another analyst. Refer to Appendix I for the steps that must be taken.

11.8.6 Concentrate all extracts to approximately 0.200 mL to remove acetone from the extract.

11.8.7 Add hexane to bring the volume to 10 mL. If the sample exhibits poor solubility in hexane, add approximately 1 mL of benzene to the vial to aid in dissolving the sample. Proceed to section 11.9.5 to perform acid cleanup.

11.8.8 Record the weights and volumes of spiking reagents used in TALS.

11.9 Extract Cleanup

11.9.1 Cleanup may not be necessary for relatively clean samples (e.g., treated effluents, groundwater or drinking water). If particular circumstances require the use of a cleanup procedure, the laboratory may use any or all of the procedures below or any other appropriate procedure. Before using a cleanup procedure, the laboratory must demonstrate that the requirements of Section 13.2 can be met using the cleanup procedure.

11.9.2 Soil, sediment and tissue sample extracts are typically taken through the following cleanup procedures: Acid cleanup, GPC and silica gel cleanup. Aqueous sample extracts are typically cleaned using GPC and silica gel cleanup, but may be cleaned using silica gel only.

11.9.3 If the sample requires a split based on the protocols listed in Table 5, the split must be performed prior to the initiation of the first cleanup procedure and prior to the addition of cleanup surrogates. For protocol 1 samples, use 5 mL of the 10 mL extract. Archive the remaining 5 mL aliquot of extract.

11.9.4 Spike each sample extract with an appropriate amount (i.e., 0.5 mL or 1.0 mL for solid, tissue and waste sample extracts; 0.20 mL for aqueous sample extracts) of the 10 ng/mL cleanup surrogate spiking solution (see section 7.12.6) prior to initiating any cleanup procedures.

NOTE: Verify that each spiking solution has not expired.

11.9.5 Acid Cleanup

11.9.5.1 Slowly add 10-20 mL of concentrated sulfuric acid to the 12 mL hexane extract in the 40 mL vial and shake for 30-60 seconds. Vent the vial frequently while shaking. Let the vial stand or centrifuge to obtain well-defined separation of acid and solvent. Remove the acid layer with a glass pipet. (Optionally, the solvent layer can be removed.) Repeat the acid washing if the solvent layer is colored. Perform a maximum of four acid washings. If solvent layer is removed, step 11.9.5.2 is not performed.

11.9.5.2 Add approximately 5 mL 5% (w/v) aqueous sodium chloride to the vial and gently shake for 30 seconds. Vent the vial frequently

while shaking. Let the vial stand until a well-defined separation has occurred and remove the aqueous layer with a glass pipet. Dry the hexane extract by adding 1 to 2 grams of sodium sulfate and swirling the vial.

11.9.5.3 Place the 40 mL vial into the N-EVAP concentration device and reduce the volume to approximately 1 mL. Solvent exchange to methylene chloride and bring to approximately 6 to 8 mL. Proceed to section 11.9.6, GPC Cleanup.

11.9.6 GPC Cleanup

11.9.6.1 Gel permeation chromatography (GPC) removes high molecular weight interferences that cause GC column performance to degrade. It should be used for all soil, sediment, tissue and waste sample extracts. It may also be used for aqueous sample extracts.

11.9.6.2 Refer to SOP KNOX-OP-0022, current revision for detailed instructions for GPC cleanup.

11.9.6.3 After GPC cleanup, concentrate the extract and solvent exchange to ~6 to 8 mL hexane using low-level KD glassware. Proceed to section 11.9.7, Silica Gel Column Cleanup.

NOTE: If concentrating aqueous sample extracts, use glassware designated for water extraction and cleanup.

CAUTION: When extracting or concentrating a sample with hexane, toluene or any mixture containing these solvents, the analyst must add the boiling chips within 5 minutes of placing the flask on the heat source in order to prevent bumping of the solvent.

11.9.7 Silica Gel Column Cleanup

11.9.7.1 Prepare 20 mm columns for each extract by placing a small amount of glass wool in the bottom of each column and then solvent rinsing with hexane. Shake out the excess hexane.

11.9.7.2 Mark the level to which the column packings will be added, starting at the top of the glass wool plug and proceeding from bottom to the top.

Layer 1 – 12 mm (2 g) of 3.3% deactivated silica gel

Layer 2 – 16 mm (4 g) of acidic silica gel

Layer 3 – 12 mm (2 g) of 3.3% deactivated silica gel

Layer 4 – 10 mm of sodium sulfate

11.9.7.3 Add the column packings to the 20 mm column in the order listed above, tapping the column to settle the contents to prevent channeling.

11.9.7.4 Add 30 mL of hexane to pre-elute the column. Do not collect the pre-eluted hexane.

11.9.7.5 When the hexane reaches the top of the sodium sulfate layer, place a solvent-rinsed 250 or 500 mL flask under the column and transfer the sample extract into the column. Quickly rinse the extract vial with a small amount of hexane and add the rinse into the column. Repeat the rinse 2 more times.

11.9.7.6 As the solvent level from the last rinse reaches the top of the sodium sulfate layer, add 70 mL of hexane into the silica gel column to elute the PCB's into the flask.

11.9.7.7 When the column stops dripping, add several PTFE boiling stones to the flask and attach a solvent-rinsed Snyder column. Concentrate the extract to > 20 mL on a heating mantle.

NOTE: Over-concentration of heated extracts is known to cause the more volatile PCB congeners to vaporize and be lost. Therefore, do not concentrate to less than 20 mL.

CAUTION: When extracting or concentrating a sample with hexane, toluene or any mixture containing these solvents, the analyst must add the boiling chips within 5 minutes of placing the flask on the heat source in order to prevent bumping of the solvent.

11.9.7.8 Transfer the extract to a 40 mL vial, rinsing the flask with a small amount of hexane and add the rinse to the 40 mL vial. Repeat the rinse 2 more times.

11.9.7.9 Place the 40 mL vial into the N-EVAP concentration device and reduce the volume to approximately 10 mL. Proceed to section 11.9.8, Final Concentration.

11.9.8 Final Concentration

11.9.8.1 Place the 40 mL vial containing the extract in the N-EVAP concentration apparatus and reduce the solvent volume to approximately 0.5 to 1.0 mL.

11.9.8.2 Label a 1.1 mL tapered mini-vial with the sample ID after checking that the vial and cap fit together properly.

11.9.8.3 For aqueous samples, add 20 µL of the 100 ng/mL internal standard spiking solution (see section 7.12.4) to the mini-vial and

mark the level on the vial. Transfer the concentrated extract into the mini-vial, rinsing 2 times with small amounts of hexane. Then reduce the extract volume back down to 20 µL. Deliver the mini-vial to the HRMS lab for analysis.

NOTE: Verify that the spiking solution has not expired.

11.9.8.4 For protocol 1 solid, sediment, tissue and waste samples, add 50 µL of the 100 ng/mL internal standard spiking solution (see section 7.12.4) to the mini-vial and mark the level on the vial. Transfer the concentrated extract into the mini-vial, rinsing 2 times with small amounts of hexane. For protocol 1 samples, reduce the extract volume to 50 µL. Deliver the mini-vial to the HRMS lab for analysis.

11.9.8.5 For samples prepared according to protocols 2, 3 and 4, add 100 µL of the 100 ng/mL internal standard spiking solution and dilute the extract with nonane to achieve the final extract volume shown in Table 5. Deliver the mini-vial to the HRMS lab for analysis.

12. Data Analysis and Calculations

12.1 Not applicable.

13. Method Performance

13.1 Method Detection Limit (MDL) - An MDL must be determined for each analyte in each routine matrix prior to the analysis of any samples. The procedure for determination of the method detection limit is given in the SOP CA-Q-S006, current revision, based on 40 CFR Part 136 Appendix B. The result of the MDL determination must support the reporting limit.

13.2 Initial Demonstration of Capability – Each analyst must perform an initial demonstration of capability (IDOC) for each target analyte prior to performing the analysis independently. The IDOC is determined by analyzing four replicate spikes (e.g., LCSs) as detailed in Eurofins TestAmerica Knoxville SOP KNOX-QA-0009, current revision.

13.3 Training Qualification: The group/team leader has the responsibility to ensure that this procedure is performed by an associate who has been properly trained in its use and has the required experience. Refer to SOP KNOX-QA-0009, current revision for further requirements for performing and documenting initial and on-going demonstrations of capability.

14. Pollution Prevention

14.1 All attempts will be made to minimize the use of solvents and standard materials.

15. Waste Management

15.1 All waste will be disposed of in accordance with Federal, State and Local regulations. Where reasonably feasible, technological changes have been implemented to minimize the potential for pollution of the environment, employees will abide by this method and the policies in section 13 of the Corporate Safety Manual for "Waste Management and Pollution Prevention."

15.2 The following waste streams are produced when this method is carried out.

- Waste methylene chloride, acetone, hexane and toluene shall be placed in the flammable waste stream, contained in a steel satellite accumulation container or flammable solvent container.
- Miscellaneous disposable glassware, chemical resistant gloves, bench paper and similar materials shall be placed in the incinerable laboratory waste stream, contained in a steel or HDPE satellite accumulation container.
- Extracted solid/tissue samples, paper funnel filters, glass wool, etc., contaminated with solvents shall be placed in the incinerable laboratory waste stream, contained in a steel or HDPE satellite accumulation container.
- Contaminated sulfuric acid used during extract cleanup shall be placed in the acidic waste stream, contained in a HDPE satellite accumulation container.
- Extracted aqueous samples, contaminated with methylene chloride shall be placed in the organic water waste stream, contained in a HDPE satellite accumulation container.

17. Miscellaneous

17.1 Modifications and enhancements from EPA Method 1668, Revisions A and B: Method 1668 is a "performance-based" method and allows for method modifications (e.g., alternate extraction, concentration and cleanup procedures, etc.) as long as the method performance criteria described in Section 13.2 are met.

17.1.1 The cleanup procedures described in this SOP have been optimized and may vary significantly from the referenced methods.

17.1.2 Additional internal standards are used in this procedure. The internal standards are listed in Table 3.

17.1.3 A solvent mixture of 1:1 hexane/acetone is used for Soxhlet extraction of solid and tissue samples that have been mixed with sodium sulfate prior to extraction.

17.1.4 Method 1668 specifies that the sample bottle is rinsed twice with 5 mL of reagent water after the sample is transferred to the separatory funnel. This procedure specifies that the sample bottle is rinsed three times with methylene chloride after the sample is transferred to the separatory funnel. This modification improves the removal of target compounds from the sample bottle.

17.1.5 The acid cleanup procedure is carried out in a 40 mL vial instead of a separatory funnel. Disposable glassware is used to decrease the risk of cross contamination. The volumes of the washes used have been adjusted for use in the 40 mL vial.

17.1.6 Extracts are stored at room temperature in the dark rather than at <10 °C. Method 1668 allows for the storage of standards at room temperature. Recovery studies performed by Cambridge Isotopes Laboratories (CIL) indicate freezing or refrigeration of standards causes problems with precipitation and irreversible adsorption to the inside surface of the vial. CIL recommends the storage of standards and extracts at room temperature as long as they are protected from exposure to UV and evaporative losses.

17.1.7 Aqueous samples with < 1% solids are extracted as received by separatory funnel. Samples with high solids content, > 1% solids, are either shaken well to thoroughly mix the sample followed by extraction by separatory funnel, or separated into two different samples for extraction and analysis, dependent upon client request.

17.1.8 Solid samples are extracted as received, with %-moisture determination

performed simultaneously. Dry weight correction to results is applied at the time of data reporting. Particle size determination and reduction as specified in method 1668 is not performed on a routine basis. These procedures are considered to be outside the scope of the laboratories routine extraction procedures and are only performed on a client specific or project specific basis. These procedures, if required, must be specified and documented in the appropriate QAPPs.

17.1.9 Tissue samples are homogenized as described in Section 11.6.1.

17.1.10 Samples are extracted immediately after spiking.

17.2 List of Tables and Appendices:

17.2.1 Table 1 – Concentration of Target Analyte PCB Congener Stock and Spiking Solutions

*PCB 170L is not included in the mix from Cambridge. It is purchased as an individual analyte and added to the mix. It is received at a concentration of 40,000 ng/mL. Bold denotes that this analyte must be added to the mix.

$^{13}C_{12}$-2,2',3,3',5,5',6-heptachlorobiphenyl	178L	50	45	45-120	40-125

1 Test concentrations are based on ng/mL in the sample extract or standard solution.

Table 5 - Assignment of Sample Preparation Protocols for Soxhlet Extraction

1668 Protocol Number	Protocol Name	Sample Amount Extracted (g)	Fraction of Extract Cleaned	TALS Final Volume-Extraction Batch (mL)	TALS Initial Volume-Split Batch (mL)	Prep Split Factor	Volume IDA Added (mL)	Volume Cleanup SU Added (mL)	Volume IS Added (µL)	Extract Final Volume (µL)
1	Clean	10	1/2	20	10	2	1	0.5 (added after split)	50	50
2	Low	2	1	10	10	1	1	1	100	100
3	Medium	1.25	1/2	20	10	2	2	1 (added after split)	100	250
4	High	1	1/4	40	10	4	4	1 (added after split)	100	500

Appendix I - Guidelines for the Spike Witnessing Process

- Make sure there are no distractions, for example, phone calls, checking samples on water bath, people coming in to ask questions.
- The person spiking must tell the person who is witnessing what is being spiked and how much.
- The person witnessing should make sure they know and understand what is to be spiked and how much. Check the paperwork to verify.
- Check the syringe for air bubbles and also check the spike volume.
- Verify that the spiking solution has not expired.
- It is a good idea to also check for cracks in the glassware.
- If client service requires spiking to occur when another analyst is not available, a witness is not required. In this case, the analyst will serve as his/her own witness, and must carefully double check the spike solutions and spike amounts added to the client samples and associated quality control samples. The analyst enters his/her initials as both the analyst and witness.

Title: GAS CHROMATOGRAPHIC ANALYSIS of PCBs BASED ON METHODS 8082 and 8082A

Printed or electronic copies of this SOP that are distributed outside of the facility are considered uncontrolled.

1. SCOPE AND APPLICATION

1.1. This SOP describes procedures to be used when SW-846 Method 8082 or 8082A are applied to the analysis of polychlorinated biphenyls (PCB) as Aroclors by GC/ECD. This SOP is applicable to extracts derived from any matrices which are prepared according to the appropriate sample extraction SOPs. PCBs are determined and quantitated as Aroclor mixes.

1.2. Table 1 lists compounds routinely determined by this method and the CAS Number. RLs are easily accessible via the Laboratory Information Management System (LIMS). Matrix interferences and/or high concentrations of PCB compounds may result in higher RLs.

1.3. Additional compounds may be amenable to this method, but they may not be reported as Ohio Voluntary Action Program (OVAP) certified data if they are not listed in 8082, and must be attested to as not-certified. If non-standard analytes are required, they must be validated.

1.4. Where requirements of this SOP are not met, including, but not limited to, Quality Control (QC) samples (Method Blank (MB) and Laboratory Control Sample (LCS)) associated to sample analytes, holding time, and preservation, the laboratory will narrate bias in the case narrative of the final report.

2. SUMMARY OF METHOD

2.1. PCBs in aqueous samples are prepared for analysis using separatory funnel extraction (SOP NC-OP-038). Solid samples are prepared using sonication or soxhlet extraction (SOP NC-OP-039 and NC-OP-040).

2.2. After the initial preparation step, the sample is introduced into the GC and the concentration of each target analyte is measured by the detector response within a defined retention time (RT) window, relative to the response of the reference standards.

3. DEFINITIONS

3.1. Refer to the Eurofins Test America Canton Quality Assurance Manual (QAM), current version, for definitions of terms and acronyms used in this document.

4. INTERFERENCES

4.1. Contamination by carryover can occur when a low concentration sample is analyzed after a high concentration sample. Co-elution of target analytes with non-targets can occur, resulting in false positives or biased high results. All glassware is cleaned per SOP NC-QA-014.

4.2. Interferences in the GC analysis can arise from many compounds which are amenable to gas chromatography and give a measurable response on the electron capture detector (ECD). Phthalate esters, which are common contaminants found in plastics, can pose a major problem in the determinations. Avoiding contact with any plastic materials minimizes interferences from phthalates.

4.3. Compounds extracted from the sample matrix to which the detector will respond, such as single-component chlorinated pesticides, including the DDT analogs (DDT, DDE, and DDD) will cause interference. A standard of the DDT analogs should be injected to determine which of the PCB or Aroclor peaks may be subject to interferences on the analytical columns used. There may be substantial DDT interference with the last major Aroclor 1254 peak in some soil and sediment samples.

4.4. All sample and associated QC extracts undergo sulfuric acid clean-up before analysis to remove non-target interfering organic compounds. Sulfur will interfere and can be removed using procedures described in SOP NC-OP-025.

4.5. Interferences co-extracted from samples will vary considerably. The presence of interferences may raise quantitation limits for individual samples. Specific cleanups may be performed on the sample extracts. These cleanup procedures are included in SOP NC-OP-025.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual, the Facility Addendum to the Corporate EH&S Manual, and this document. Eye protection that prevents splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Refer to the Eurofins TestAmerica Canton Corporate Environmental Health and Safety Manual for a complete description of personal protection equipment.

5.2. Cut-resistant gloves must be worn when doing any other task that presents a strong possibility of getting cut. Disposable gloves that have become contaminated must be removed and discarded; other gloves must be cleaned immediately. Nitrile gloves provide adequate protection against the solvents used in this method.

5.3. The following is a list of the materials used in this method, which have a serious or significant hazard rating. NOTE: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the Safety Data Sheet (SDS) for each of the materials listed in the table. A complete list of materials used in the method can be found in the Reagents and Standards section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Company Confidential & Proprietary

Material	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Acetone	Flammable	1000 ppm-TWA	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Hexane	Flammable Irritant	500 ppm-TWA	Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Vapors may cause irritation to the skin and eyes.
Methylene Chloride	Carcinogen Irritant	25 ppm-TWA 125 ppm-STEL	Causes irritation to respiratory tract. Has a strong narcotic effect with symptoms of mental confusion, light-headedness, fatigue, nausea, vomiting and headache. Causes irritation, redness and pain to the skin and eyes. Prolonged contact can cause burns. Liquid degreases the skin. May be absorbed through skin.
Note: Always add acid to water to prevent violent reactions.			
2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.4. Aroclors have been classified as a potential carcinogen under OSHA. Concentrated solutions of Aroclors must be handled with extreme care to avoid excess exposure. Contaminated gloves and clothing must be removed immediately. Contaminated skin surfaces must be washed thoroughly.

5.5. All ^{63}Ni sources (ECD) must be leak tested every six months, or in accordance with the manufacturer's general radioactive material license.

5.6. All ^{63}Ni sources must be inventoried every six months. If a detector is missing, the EH&S Director must be immediately notified and a letter sent to the NRC or local state agency.

5.7. Exposure to chemicals must be limited as much as reasonably achievable. All samples with stickers that read "Caution/Use Hood!" must be opened in the hood. Contact the EH&S Coordinator if this is not possible. Solvent and waste containers must be kept closed unless transfers are being made.

5.8. Opened containers of neat standards must be handled in a fume hood.

5.9. Sample extracts and standards, which are in a flammable solvent, must be stored in an explosion-proof refrigerator.

5.10. When using hydrogen gas as a carrier, all precautions listed in the CSM must be observed.

5.11. Standard preparation and dilution must be performed inside an operating fume hood.

5.12. The gas chromatograph contains zones that have elevated temperatures. The analyst needs to be aware of the locations of those zones, and must cool them to room temperature prior to working on them.

5.13. There are areas of high voltage in the gas chromatograph. Depending on the type of work involved, either turn the power to the instrument off, or disconnect it from its source of power.

Company Confidential & Proprietary

5.14. All work must be stopped in the event of a known or potential compromise to the health and safety of a Eurofins TestAmerica associate. The situation must be reported immediately to the EH&S Coordinator and the Laboratory Supervisor.

6. EQUIPMENT AND SUPPLIES

6.1. Gas Chromatograph (GC) equipped with Electron Capture Detectors (ECDs)

6.2. Software: ChemStation or equivalent

6.3. Refer to Table 2 for analytical columns and run conditions

6.4. Microsyringes and syringes: various sizes, for standards preparation, sample injection, and extract dilution

6.5. Solvent: Hexane

6.6. Autosampler vials, inserts, and caps

6.7. Class A volumetric flasks: various sizes

6.8. Transfer pipettes: disposable

6.9. VOA vials

6.10. Carrier gas: Hydrogen

6.11. Makeup gas: Nitrogen

7. REAGENTS AND STANDARDS

7.1. Stock Standards: Stock standards are purchased as certified solutions or prepared from pure solutions.

7.1.1. Stock standard solutions are stored as recommended by the manufacturer. All stock standards must be protected from light. Stock standard solutions must be brought to room temperature before using.

7.1.2. Stock standard solutions must be replaced after one year.

7.1.3. Expiration times for all standards are measured from the time the standard is prepared or from the time that the standard ampoule is opened, if the standard is supplied in a sealed ampoule. If vendor-supplied standard has an earlier expiration date then the vendor's expiration date is used. Refer to SOP NC-QA-017, Standards and Reagents, for additional information. The standard preparation information is detailed in the LIMS standards and reagents module.

7.2. Calibration Standards

7.2.1. PCB Calibration Standards

7.2.1.1. PCB calibration standards are prepared as dilutions of the stock standards. Surrogates and internal standards are used as specified in the method. PCB calibration solutions must be refrigerated at 4° C ± 2° C and protected from light. The standards must be replaced at least every six months or sooner if comparison with check standards indicates a problem.

7.2.1.2. See the LIMS Reagent module for details on standard concentration and preparation.

7.3. Surrogate Standards

7.3.1. Tetrachloro-m-xylene (TCMX) and decachlorobiphenyl (DCB) are the surrogate standards. Refer to the LIMS for details of surrogate standards.

7.4. Internal Standard

7.4.1. The internal standard used for PCB analysis is 1-Bromo-2-nitrobenzene (BNB)

Note: The OVAP program prohibits the use of re-verified standards. If no other standard is available, this must be narrated and the data marked as “not certified” on the affidavit.

8. SAMPLE COLLECTION, PRESERVATION AND STORAGE

8.1. Unless otherwise specified by regulatory or client programs, holding time for PCB samples (regardless of matrix) is 1 year.

8.2. Sample extracts are stored at 4 ± 2°C until analysis is complete. The holding time for PCB sample extracts is 40 days.

9. QUALITY CONTROL

9.1. Batch definition

9.1.1. The batch is a set of up to 20 samples of the same matrix processed at the same time using the same procedures and reagents. The Quality Control batch must contain a matrix spike / spike duplicate (MS/MSD), a Laboratory Control Sample (LCS), and a method blank (MB). Laboratory generated QC samples (Method Blank, LCS and MS/MSD do not count towards the maximum 20 samples in a batch. Field QC samples are included in the batch count. In some cases, at client request, the MS/MSD may be replaced with an MS and an un-spiked sample duplicate (DU).

9.2. Method Blank (MB)

9.2.1. For each batch of samples, analyze an MB. The MB consists of reagent water for aqueous PCB samples and sodium sulfate for PCB soils tests and all surrogates required for the analysis. Refer to SOPs NC-OP-038, NC-OP-039, and NC-OP-040 for details.

9.2.2. The MB must not contain any analyte of interest at, or above, the reporting limit or at, or above, 5% of the measured concentration of that analyte in the associated samples, whichever is higher.

Note: Some programs require that the MB be clean to ½ the RL. Method notes should inform the analyst if the samples are part of a special program. Analysts are responsible for checking the program requirements.

9.2.3. Corrective action

9.2.3.1. Corrective action may include re-analysis of the MB. If the re-analysis fails to meet criteria, re-extraction and re-analysis of samples associated with an unacceptable MB is required when concentrations greater than the RL are detected in the samples.

9.2.3.2. If there is no target analyte greater than the RL in the samples associated with an unacceptable MB, the data may be reported with qualifiers.

9.3. **Note:** For Ohio VAP projects, the MB results must be below the reporting limit or the samples must be re-extracted. The exceptions are as follows: (a) insufficient sample for re-extraction (b) expired holding times, or (c) the analytes detected in the blank are non-detect in the associated samples. Under the above circumstances, results may be reported. **Note:** the 10x rule does NOT apply for OVAP.Laboratory Control Samples (LCS)

9.3.1. For each batch of samples, analyze an LCS. The LCS contains a mix of Aroclors 1016 and 1260 and all surrogates required for the analysis. The LCS standard contains the same analytes as the matrix spike. If any LCS analyte is outside the laboratory established historical control limits, corrective action must occur.

9.3.2. Corrective Action

9.3.2.1. Corrective action may include re-analysis of the LCS. If the re-analysis fails to meet criteria, re-extraction and re-analysis of the batch may be needed. If the LCS is biased high, samples that have no analytes detectable above the RL may be reported with proper narration.

Note: For Ohio VAP samples, re-analyze an aliquot of the LCS to verify the outlier; if the LCS exhibits the same anomaly upon re-analysis, the sample batch must be re-extracted and re-analyzed. The exceptions are as follows: (a) insufficient sample for re-extraction (b) expired holding times, or (c) the LCS is biased high and the samples have no detections above the RL for those analytes. Under the above circumstances, results may be reported with proper narration.

9.3.3. LCS compound lists and surrogates are included in the reagent module of the LIMS.

9.4. Matrix Spikes/Spike Duplicates (MS/MSD)

9.4.1. For each QC batch, analyze an MS/MSD. Compare the percent recovery and relative percent difference (RPD) to those in the laboratory-specific historically generated limits.

9.4.2. Corrective Action

9.4.2.1. If any individual recovery or RPD falls outside the acceptable range, corrective action must occur unless samples for this compound are ND. The initial corrective action must be to check the recovery of that analyte in the LCS. Generally, if the recovery of the analyte in the LCS is within limits, adverse matrix effect is indicated, the laboratory operation is in control and analysis may proceed.

9.4.2.2. If the recovery for any component is outside QC limits for both the MS/MSD and the LCS, the laboratory process is out of control and corrective action must be taken.

9.4.3. The MS/MSD must be analyzed at the same dilution as the un-spiked sample.

9.5. Surrogates

9.5.1. Surrogates are added to all samples, and batch QC during the preparation procedure. Surrogates are added to instrument QC for the 1016/1260 Aroclor mix, which includes the calibration standards, and the CCVs. Surrogate recoveries in samples and QC samples must be assessed to ensure that recoveries are within established limits.

9.5.2. Method Blank

9.5.2.1. Surrogates are added to the MB and the MB is carried through the entire analytical procedure. The MB must have acceptable surrogate recoveries. If surrogate recoveries are not acceptable, the data must be evaluated to determine if the method blank has served the purpose of demonstrating that the analysis is free of contamination. If surrogate recoveries are low and there are reportable analytes in the associated samples, re-extraction of the MB and affected samples will normally be required. If surrogate recoveries are high, and the samples are non-detect, the data may be reported with proper narration.

9.5.3. LCS

9.5.3.1. The LCS must have acceptable surrogate recoveries. If surrogate recoveries are not acceptable, the data must be evaluated to determine if the LCS has served the purpose of demonstrating effectiveness of the extraction process. If surrogate recoveries are low, re-extraction of the LCS and affected samples will normally be required. None of the surrogate recoveries can fall below 10% in the

LCS. If surrogate recoveries are high, and the samples have no detections above the RL, the data may be reported with proper narration.

9.5.4. Instrument QC

9.5.4.1. Surrogates in the 1016/1260 calibration standards must meet the same criteria as the ICAL. See section 10 for ICAL criteria.

9.5.4.2. Surrogates in the CCVs must have a %D of <15% for Method 8082, and <20% for Method 8082A.

9.5.4.3. Corrective actions for failing surrogates in the instrument QC are discussed in section 10.

9.5.5. Samples

9.5.5.1. If either surrogate is outside limits, the following corrective actions must take place (except for dilutions greater than 5X):

9.5.5.1.1. Check all calculations for error.

9.5.5.1.2. Ensure instrument performance is acceptable.

9.5.5.1.3. Recalculate the data and/or re-analyze the extract if either of the above checks reveals a problem.

9.5.5.2. It is only necessary to re-prepare / re-analyze a sample once to demonstrate poor surrogate recovery is due to matrix effect, unless the analyst believes that the repeated out-of-control results are not due to matrix effect.

9.5.5.3. If the surrogates are out of control for the sample and MS/MSD, then matrix effect has been demonstrated for that sample and re-preparation is not necessary. If the sample is out of control and the MS/MSD is in control, then re-preparation or flagging of the data is required. Re-preparation includes the parent sample and the MS/MSD.

9.5.6. **Note:** For Ohio VAP projects all surrogates must be within acceptance criteria. For surrogate outliers, the analyst should either: (a) re-analyze, (b) re-prep/re-analyze, or (c) perform a dilution. When there is an obvious interference causing the surrogate outlier that the analyst knows a corrective action would not resolve the issue, flag the data with a qualifier indicating matrix interference. The exceptions for re-prep/re-analysis are as follows: (a) insufficient sample for re-analysis, or (b) the surrogates are biased high and the samples are non-detect. Under the above circumstances, results may be reported. All batch QC samples must pass surrogate criteria or the batch (samples and QC) must be re-analyzed if sufficient volume and holding time remains.

Company Confidential & Proprietary

9.5.7. Refer to Eurofins TestAmerica Canton QC Program document (Policy QA-003) for further details of the corrective actions.

9.6. Internal Standard (IS)

9.6.1. This procedure is an IS procedure. 1-Bromo-2-nitrobenzene (BNB) is the internal standard used.

9.6.2. Prior to analysis, the IS must be added to all standards, field sample extracts, and QC sample extracts. The concentration of the IS must be the same in all calibration standards, field sample extracts, and QC sample extracts. A concentration of 0.05 ug/mL is used.

9.6.3. The response of the IS in the ICV/CCV must be within 50-200% of the response of the IS in the CCV-level standard in the initial calibration sequence. If the response is outside of this range, the analysis of the ICV/CCV must be repeated and any samples associated with the ICV/CCV must also be re-analyzed. Repeated failure of the IS response will require recalibration.

9.6.4. The response of the IS in the samples and batch QC items must be within 50-200% of the response of the previous CCV. If the response is outside of the range, corrective action must be taken which may include re-analysis of the extract, re-spiking the extract with IS and re-analysis, or re-calibration of the analytical system. Obvious matrix interferences are qualified and noted in an NCM.

9.7. **Note:** For OVAP projects, samples with failing internal standards must be re-analyzed unless matrix interference is apparent. If matrix interference is apparent, dilute the sample with hexane. When there is obvious interference causing the IS failure that corrective action will not remedy, data must be narrated as matrix interference. If the QC has failing internal standards, the associated batch (samples and batch QC) must be re-spiked and re-analyzed.

9.8. Control Limits

9.8.1. Control limits are established by the laboratory as described in SOP NC-QA-018.

9.8.2. Laboratory control limits are internally generated and updated periodically unless method specified. Control limits are easily accessible via the LIMs.

10. CALIBRATION AND STANDARDIZATION

10.1. Internal or external calibration may be used. Prepare standards containing each analyte of interest at a minimum of five concentration levels. The low-level standard must be at, or below, the reporting limit. The other standards define the working range of the detector.

10.2. The initial PCB calibration must include at least one level with 1016 analyzed separately for pattern recognition purposes. This run does not have to be part of the calibration.

10.3. A new calibration curve must be generated after major changes to the system or when the continuing calibration criteria cannot be met. Major changes include new columns or replacing the ECD detector. A new calibration is not required after clipping the column, replacing the septum or syringe, or other minor maintenance, unless CCV criteria cannot be met.

10.4. With the exception of section 10.5 below, it is not acceptable to remove points from a calibration curve for the purpose of meeting criteria, unless the points are the highest or lowest on the curve and the reporting limit and/or linear range is adjusted accordingly. In any event, at least five points must be included in the calibration curve. Quadratic (second order) calibrations require at least six points.

Note: Quadratic calibrations are not acceptable for PCB analysis for OVAP projects.

10.5. A level may be removed from the calibration if the reason can be clearly documented (for example, a broken vial or no purge run). A minimum of five levels must remain in the calibration. The documentation must be retained with the initial calibration. Alternatively, if the analyst believes that a point on the curve is inaccurate, the point may be re-analyzed and the re-analysis used for the calibration. All initial calibration points in a single calibration curve must be analyzed without any changes to instrument conditions, and all points in a single calibration curve must be analyzed within 24 hours.

10.6. Internal Standard Calibration

10.6.1. Internal standard calibration involves the comparison of instrument responses from the target compounds in the sample extract to the response of a specific standard added to the r sample extract prior to injection. This specific standard is referred to as the internal standard (IS) because it is contained within the aliquot of the sample extract and is actually injected into the instrumentation. The ratio of the peak area (or height) of the target compound in the sample extract to peak area (or height) of the IS in the sample extract is compared to a similar ratio derived for each calibration standard. The ratio is termed the response factor (RF), or relative response factor (RRF).

10.6.2. When preparing calibration standards for use with internal standard calibration, add the same amount of internal standard solution to each calibration standard, such that the concentration of each internal standard is constant across all of the calibration standards, whereas the concentrations of the target analytes will vary. The mass of the internal standard added to each sample extract immediately prior to injection into the instrument must be the same as the mass of the internal standard in each calibration standard. The volume of the solution spiked into sample extracts should be such that minimal dilution of the extract occurs.

10.6.3. Prepare calibration standards at a minimum of five concentration levels for each parameter of interest and each surrogate. Six standards must be used for a quadratic least squares calibration. Add the appropriate amount of the IS mixture to result in a 0.05 ug/mL concentration. The low standard must be at or below the reporting limit

10.6.4. Calculate response factors (RF), average response factors, and the percent RSD of the response factors for each compound and surrogate using the equations in Section 12.

10.7. External standard calibration

10.7.1. Quantitation by the external standard method assumes a proportional relationship between the analyte or surrogate response and the concentration that is the same in all of the calibration standards and the samples. To use this approach, introduce each calibration standard into the GC using the technique that will be used for samples. The ratio of the peak height or area response to the mass or concentration injected is used to prepare a calibration curve.

10.8. Calibration Curve Fits

10.8.1. The calculations for all calibration curve fits are found in section 12.

10.8.2. Weighted linear regression, average calibration factor, non-weighted linear regression, or quadratic curves may be used to fit the data. - Average calibration factor is the preferred calibration model used for PCB.

10.9. Average calibration factor (CF) / response factor (RF)

10.9.1. The average CF (external calibration) or RF (internal standard) may be used if the average percent relative standard deviation (% RSD) of all the CFs / RFs taken together is $\leq$ 20%. The average % RSD is calculated by summing the %RSD value for each peak and dividing by the total number of peaks.

10.10. Linear Regression / Weighted Linear Regression

10.10.1. Linear / weighted linear regressions must have a minimum of 5 calibration levels with the lowest being at or below the reporting limit. The correlation coefficient (r) must be >0.990. The ICV %D must be <20%, and the CCV %D must be <15% for Method 8082. For Method 8082A, the criteria for both ICV and CCV are < 20% % D.

10.11. Quadratic Curve

10.11.1. A quadratic calibration curve must only be used if the analyst has reason to believe that a linear or average model does not fit the normal concentration-to-response behavior of the detector. A quadratic curve fit may be used only if the compounds have historically exhibited a non-linear response and cannot be used to extend the calibration range for compounds that normally exhibit a linear response, but within a narrower calibration range.

10.11.2. A quadratic calibration curve must have a minimum of 6 calibration levels with the lowest being at or below the reporting limit. The coefficient of determination (r^2) must be > 0.990.

10.12. Evaluation of Calibration Curves

10.12.1. The percent relative standard error (% RSE) from the calibration curve is used to evaluate the initial calibration. This provides a measure of how much error is associated with using the calibration curve for quantitation.

10.12.2. The least squares regression line is calculated and used to calculate the predicted concentration for each level.

Note: When average calibration factors are used, %RSE is equivalent to %RSD.

10.13. The following requirements must be met for any calibration to be used.

10.13.1. Response must increase with increasing concentration.

10.13.2. If a curve is used, the calculated intercept of the curve at zero response must be less than ± the reporting limit for the analyte.

10.13.3. The average Relative Standard Error (RSD for average response factors) of the calibration points from the curve used must be ≤ 20%.

10.13.4. Some data systems will not measure the %RSE from a linear or quadratic fit. For the linear case, the correlation coefficient may be used as an alternative to the %RSE, and must be greater than or equal to 0.990. For the quadratic case the Coefficient of Determination (COD) may be used, and must be greater or equal to 0.990.

Note: The Relative Standard Error (RSE) is superior to the Correlation Coefficient (*r*) and Coefficient of Determination (r^2) for testing the fit of a set of calibration points to a line. The lower points on a curve have little effect on *r.* As a result, a curve may have a very good correlation coefficient (>0.990) while also having > 100% error at the low point.

Note: The surrogates must be judged against these same criteria.

10.14. Weighting of Data Points

10.14.1. In linear and quadratic calibration fits, the points at the lower end of the calibration curve have less absolute variance than points at the high concentration end of the curve. This can cause severe errors in quantitation at the low end of the calibration. However, in environmental analysis, accuracy at the low end of the curve is very important. For this reason, it is preferable to increase the weighting of the lower concentration points. $1/Concentration^2$ weighting (often called $1/X^2$ weighting) will improve accuracy at the low end of the curve and must be used when an average calibration factor is not appropriate, as long as the data system has this capability.

10.15. Initial Calibration

10.15.1. A minimum five-point calibration of all Aroclors is generated. The low-level standard must be at or below the reporting limit. The other standards define the working range of the detector.

10.15.2. If any Aroclor is determined above the calibration range, the extract must be diluted and re-analyzed.

10.15.3. The surrogate calibration curve is included in the calibration from the Aroclor 1016/1260 mix.

10.16. Initial Calibration Verification (ICV)

10.16.1. The ICVs are analyzed immediately after an initial calibration. The acceptance criterion is ± 20%.

10.16.2. If the overall average percent drift of all analytes is greater than ±20%, corrective action must be taken. This may include clipping the column, changing the liner, or other minor instrument adjustments, followed by re-analyzing the standard. If the overall average percent drift still varies by more than ±20%, a new calibration curve may be required.

10.17. Continuing Calibration Verification (CCV)

10.17.1. It is not necessary to run a calibration verification standard at the beginning of the sequence if samples are analyzed immediately after the completion of the initial calibration.

10.17.2. Mid-level standards covering all Aroclors of interest are used for the calibration verifications.

10.17.3. CCVs are analyzed for all Aroclors at the beginning of each day, and at the beginning of each 12 hour shift.

10.17.4. Retention times windows are updated daily from the opening CCVs.

10.17.5. Evaluate the resolution of the triplet towards the end of the 1260 chromatogram in the opening CCV. There must be at least 25% resolution on one of the two columns used.

10.17.6. The Aroclor 1016/1260 CCV is analyzed after every 20 injections. Depending on the type of samples, it may be advisable to analyze verifications more frequently in order to minimize reruns.

Note: Various programs require a CCV every 10 injections. Analysts are responsible for checking the program requirements.

10.17.7. For Method 8082A, the CCV acceptance criterion is ± 20%. For Method 8082, the CCV acceptance criterion is ±15%.

10.17.8. A bracketing CCV is not required for IS calibrations.

10.17.9. Samples quantitated against an external standard calibration must be bracketed by a 1016/1260 CCV.

Company Confidential & Proprietary

10.17.10. Corrective Actions for Continuing Calibration Failures

10.17.10.1. If a CCV fails to meet criteria, corrective action must be taken. This may include clipping the column, changing the liner, or other minor instrument adjustments, followed by re-analyzing the standard. If the re-analysis still fails to meet criteria, a new calibration curve may be required.

10.17.10.2. Samples quantitated against an external standard calibration must be bracketed with passing CCVs. All samples analyzed immediately prior to, and immediately following the failing CCV must be re-analyzed.

10.17.10.3. Sample results that are below the reporting limit may be reported when a CCV is biased high. Such action must be addressed in the case narrative.

10.18. Retention Time Windows

10.18.1. Retention time (RT) windows must be determined for all analytes.

10.18.2. Initial determination of Retention time windows

10.18.2.1. The center of the retention time (RT) window shall be updated based on the middle level in the initial calibration or the first CCV in the daily analytical sequence, whichever is more recent.

10.18.2.2. Evaluate the deviation from expected retention time for each analyte in at least three CCV and/or LCS samples spread over at least 72 hours. Calculate the standard deviation of these retention times.

10.18.2.3. If three days of analytical data are not available, use a default RT window of 0.01 minutes. At the end of the batch evaluate all CCVs and LCS in the batch. If necessary, widen the window such that all analytes fall within the RT window. Reprocess the batch using the new RT windows.

10.18.2.4. Multiply the standard deviation by 3. This is the retention time window, unless the result is less than 0.01 min, in which case the window is set at 0.01 min.

10.18.2.5. An alternative method to determine the retention time window is to multiply the maximum deviation of all points by 1.5. The minimum retention time window is 0.01 minutes. For example, if the maximum RT deviation for a specific analyte is 0.008 min, then the RT window is set at ± 0.012 min.

Note: For multi-component analytes, like Aroclors, the maximum deviation must be evaluated for each of the 3 to 6 major peaks used for sample calculations.

10.18.2.6. If the retention time windows for analytes of interest overlap, the analyte must be confirmed on a dissimilar column.

10.18.3. Ongoing evaluation of retention time windows

10.18.3.1. Evaluate the retention time windows on an ongoing basis. The center of the RT window is updated on the first CCV of the day and verified every 12 hours. All analytes for all subsequent CCVs, LCS and matrix spikes must fall within the retention time window (except as discussed below).

10.18.3.2. Matrix spike analytes may fall outside the retention time window if there is a large non-target peak coeluting with the analyte in the matrix spike.

10.18.3.3. If any analytes fall outside the retention time window in CCVs, LCS or matrix spikes (except as discussed above for matrix spikes) then the RT windows for those analytes shall be widened to the minimum degree required for the analyte to fall within the RT window. All samples in the batch shall be reprocessed with the new RT window, and the wider RT window shall remain in place for subsequent batches.

10.18.3.4. Retention time windows should be reliably narrower than +/- 0.03 min. If RT windows wider than this are necessary, the instrument should be evaluated and maintenance performed as needed. Subsequent to maintenance, RT windows shall be narrowed to the extent that is consistent with the data obtained.

11. PROCEDURE

11.1. Procedural variations are allowed only if deemed necessary in the professional judgment of QA, operations supervisor, or designee to accommodate variation in sample matrix, chemistry, sample size, or other parameters. Any variation in procedure must be completely documented using a Nonconformance Memo. The Nonconformance Memo must be filed in the project file. The nonconformance is also addressed in the case narrative. Any unauthorized deviations from this procedure must also be documented as a nonconformance with a cause and corrective action described.

Note: Procedural deviations are not allowed for Ohio VAP Projects.

11.2. Extraction

11.2.1. Extraction procedures are referenced in the SOPs NC-OP-038, NC-OP-039, and NC-OP-040, current revisions.

11.3. Suggested gas chromatographic conditions are given in Table 2.

11.4. Allow extracts to warm to ambient temperature before injection.

11.5. Sample Analysis

11.5.1. Run between 2 and 5 instrument blanks before calibration or running the -opening CCV. The instrument blanks consist of Hexane, and are used to clean the instrument prior to analysis.

Note: Instrument blanks are not surrogated.

11.5.2. For samples analyzed by IS calibration models, transfer 100 µL of the extract to an autosampler vial and add 5 µL of the IS solution or equivalent volumes to give an IS concentration of 0.05 ug/mL. The concentration of the internal standard must be the same in all calibration samples, field samples, and QC samples. -.

11.5.3. For samples analyzed by external calibration models, transfer an adequate amount of extract into an autosampler vial and load the vials onto the instrument.

11.5.4. The sample extract must be injected using the same injection volume used for the calibration standards.

11.5.5. If highly contaminated samples are expected, it is acceptable to analyze solvent blanks or primers at any point in the run. Solvent blanks may not be routinely analyzed prior to QC samples.

11.6. Identification of Aroclors

11.6.1. The laboratory performs Update IV's recommended analysis of DDT and analogs DDD and DDE daily to assure there is no interference with major 1254 peaks.

11.6.2. Retention time windows are used for the identification of Aroclor peaks, but the "fingerprint" produced by major peaks of those analytes in the standard is used to differentiate the identity of any Aroclor that may be present. The ratios of the areas of the major peaks are also taken into consideration. Analyst judgement must weigh heavily in the identification of Aroclor patterns. Identification may be made even if the retention times of the peaks in the sample fall outside of the retention time windows of the standard, if the fingerprint (retention time and peak ratios) resembles the standard chromatogram.

11.7. Quantitation of Aroclors

11.7.1. For PCB analysis, the preferred reporting approach is the primary column approach. Dependent upon client program, the higher or lower result may be used for quantitation. Results may be report from the confirmation column when matrix interference is present and impacts either the IS or specific compounds and the RPD between columns.

11.7.2. Use 3-5 major peaks for quantitation

11.7.3. If the analyst believes that a combination of Aroclor 1254 and 1260 or a combination of 1242, 1248 and 1232 is present, then only the predominant Aroclor is quantitated and reported, but the suspicion of multiple Aroclors is discussed in the narrative. If well-separated Aroclor patterns are present, then multiple Aroclors may be quantitated and reported.

11.7.4. Every sample undergoes dual column analysis; however, reporting the second column results will only be performed when requested by the client or regulatory program. The appearance of the multiple characteristic peaks in the sample usually serves as a confirmation of the presence of an Aroclor.

11.8. Surrogate recovery results are calculated and reported for decachlorobiphenyl (DCB) and tetrachloro-m-xylene (TCMX). Corrective action is necessary if either DCB or TCMX are outside of acceptance limits. Samples may be reported when there is obvious matrix interference present; however, such action must be included in the case narrative. See section 9.5 for further information on surrogate recovery.

11.9. Dilutions

11.9.1. Samples may be screened to determine the appropriate dilution for the initial run.

11.9.2. If concentrations of any analytes exceed the working range as defined by the calibration standards, then the sample must be diluted and re-analyzed.

11.9.3. Dilutions must target the most concentrated analyte in the upper half (over 50% of the high level standard) of the calibration range when allowed by sample matrix.

11.9.4. It may be necessary to dilute samples due to matrix. Analyst judgment is required to determine the most concentrated dilution that will not result in instrument contamination.

11.9.5. If the sample is run at a dilution and only minor matrix interferences are observed, then the sample should be re-analyzed at a more concentrated dilution in an attempt to target the upper half of the calibration range.

11.9.6. The most concentrated dilution with no target compounds above the calibration range should be reported. Other dilutions may be reported at client request if the lower dilutions will not cause detector saturation, column overload, or carryover. Analyst judgment and client site history will be factors in the reporting of multiple dilutions.

11.10. Interferences

11.10.1. If peak detection is prevented by interferences, then elevation of reporting levels and/or lack of positive identification must be addressed in the case narrative.

Company Confidential & Proprietary

11.11. Reporting of Data

11.11.1. The preferred reporting approach is the primary column approach, where the analyst evaluates the opening CCVs and designates a primary column to report data from. All data is reported from the primary column in an analytical run, as long as the RPD between columns is less than 40%.

11.11.2. When the RPD between the primary and confirmation column exceeds 40%, it is an indication of likely matrix interference. Every situation is different and the analyst must rely on their experience in choosing which data to report. Two common issues are addressed below:

11.11.2.1. When there is interference with an analyte of interest, the higher result is likely biased due to matrix; therefore, the lower result is reported.

11.11.2.2. When there is interference with the IS, the results on the entire column are biased; therefore, the column without interference in the IS may be the better result. Dilution and reanalysis may be required when there is interference with the IS.

11.12. Analytical Documentation

11.12.1. Record all analytical information in LIMS, including any corrective actions or modifications to the method.

11.12.2. Record all standards and reagents in the LIMS Reagents module. All standards and reagents are assigned a unique number for identification.

Note: When making new standards, it is required that all information entered into TALS is reviewed by another analyst.

11.12.3. Record sample and associated QC information in the LIMs. Level I and Level II technical reviews are performed in LIMS.

12. DATA ANALYSIS AND CALCULATIONS

12.1. Calibration Calculations

12.1.1. Calibration Factor (CF) for external calibration and Response Factor (RF) internal standard calibration

$$CF = \frac{A_s}{C_s}$$

Where A_s = Peak area (or height) in standard

C_s = Concentration of standard injected

$$RF = \frac{A_x C_{is}}{A_{is} C_x}$$

Where: A_x = Peak Area (or height) of the analyte or surrogate

A_{is} = Peak Area (or height) of the internal standard

C_x = Concentration of the analyte or surrogate (µg/L)

C_{is} = Concentration of the internal standard (µg/L)

12.1.2. Evaluating the linearity of the initial calibration using an Average Calibration fit:

$$Mean\ CF = \overline{CF} = \frac{\sum_{i=1}^{n} CF_i}{n}$$ (external calibration)

$$Mean\ RF = \overline{RF} = \frac{\sum_{i=1}^{n} RF_i}{n}$$ (internal standard calibration)

Where n = the number of calibration standards

$$Standard\ Deviation\ (SD) = \sqrt{\frac{\sum_{i=1}^{n}(CF_i - \overline{CF})^2}{n-1}}$$ (external calibration)

$$SD = \sqrt{\frac{\sum_{i=1}^{n}(RF_i - \overline{RF})^2}{n-1}}$$ (internal standard calibration)

Where n = the number of calibration standards

$$\%RSD = \frac{SD}{\overline{CF}} \times 100$$ (external)

$$\%RSD = \frac{SD}{\overline{RF}} \times 100$$ (internal standard)

Note: If the RSD of the calibration or response factors is less than or equal to 20%, the average calibration or response factor may be used to determine sample concentrations.

12.1.3. Percent Difference (%D)

$$\%D = \frac{CF_c - \overline{CF}}{\overline{CF}} \times 100$$

Where CF_c = The calibration factor from the CCV or ICV

$\overline{CF}$ = The average calibration factors from the initial calibration

$$\%D = \frac{RF_c - \overline{RF}}{\overline{RF}} \times 100$$

Where RF_c = The response factor from the CCV or ICV

$\overline{RF}$ = The average response factors from the initial calibration

12.2. Linear regressions

y = ax + b

Where y = Instrument response (area or height)

a = Slope of the line

x = Concentration of the calibration standard

b = The intercept

12.2.1. For internal standard the equation for weighted or non-weighted linear regression is:

$$C_s = \frac{\left(\frac{A_s C_{is}}{A_{is}} - b\right)}{a}$$

Where A_s = Area (or height) of the peak for the target analyte in the sample

A_{is} = Area (or height) of the peak for the internal standard

C_s = Concentration of the target analyte in the calibration standard

C_{is} = Concentration of the internal standard

a = Slope of the line

b = The intercept

12.2.2. Correlation Coefficient

$$r = \frac{\sum d_x d_y}{\sqrt{\sum d_x^2 \sum d_y^2}}$$

Where:

d_x = deviation of x from the mean

d_y = deviation of y from the mean

12.2.3. Relative Standard Error (%RSE)

$$\%RSE = 100\% \times \sqrt{\frac{\sum_{i=1}^{n} \left[\frac{C_i - PC_i}{C_i}\right]^2}{(n-p)}}$$

Where: n = Number of points in the curve
p = Number of parameters in the curve (= 1 for average response factor, 2 for linear, 3 for quadratic)
C_i = True concentration for level i
PC_i = Predicted concentration for level i

12.2.4. Percent Drift for CCV and ICV

$$\%Drift = 100\% \times \frac{C_{actual} - C_{found}}{C_{actual}}$$

Where: C_{actaul} = Known concentration in standard

C_{found} = Measured concentration in CCV or ICV

12.2.5. Curve weighting may be beneficial for linear regressions. Curve weighting improves the linearity at the low end of the calibration curve. Weighted curve calculations are similar to the unweighted calculations above, but use 1/x or $1/x^2$ (where x = concentration) to determine the regression instead of the concentration.

12.3. Quadratic calibration fit (only to be used if applicable)

$y = ax^2 + bx + c$

Where: y = Response

x = Concentration

a = Curvature

b = Slope

c = Intercept

12.3.1. Coefficient of Determination (COD)

$$COD = r^2 = \frac{\sum_{i=1}^{n}(y_{obs} - \bar{y})^2 - \left(\frac{n-1}{n-p}\right)\sum_{i=1}^{n}(y_{obs} - y_i)^2}{\sum_{i=1}^{n}(y_{obs} - \bar{y})^2}$$

Where: y_{obs} = Observed response (area) for each concentration from each initial calibration standard

$\bar{y}$ = Mean observed response from the initial calibration

y_i = Calculated response at each concentration from the initial calibration

n = Total number of calibration points

p = Number of adjustable parameters in the polynomial equation (2 for second order polynomial)

12.4. Concentration

12.4.1. Aqueous

$$Concentration\ \left(\frac{\mu g}{L}\right)\frac{C_{ex}V_t}{V_o}$$

Where C_{ex} = On-column concentration as determined in sections 12.1-12.3. (ng/µL)

V_t = Final extract volume (µL)

V_o = Initial sample volume (mL)

12.4.2. Non-aqueous

$$Concentration\ \left(\frac{\mu g}{Kg}\right) = \frac{C_{ex}V_t}{W_s D}$$

Where C_{ex} = On-column concentration as determined in sections 12.1-12.3. (ng/µL)

V_t = Final extract volume (µL)

W_s = Initial sample mass (g)

D = (100-%moisture in sample) / 100 for dry weight basis

or

D = 1 for a wet weight basis

13. METHOD PERFORMANCE

13.1. Method Detection Limit

13.1.1. Each laboratory must generate a valid method detection limit for each analyte of interest. The MDL must be below the reporting limit for each analyte. The procedure for determination of the method detection limit is given in 40 CFR Part 136, Appendix B, and further defined in SOP CA-Q-S-006.

13.2. Training Qualification

13.2.1. The Group/Team Leader has the responsibility to ensure an analyst who has been properly trained in its use and has the required experience performs this procedure.

14. POLLUTION PREVENTION

14.1. It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage, and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention".

15. WASTE MANAGEMENT

15.1. All waste must be disposed of in accordance with Federal, State and Local laws and regulations. Where reasonably feasible, technological changes have been implemented to minimize the potential for pollution of the environment. Employees must abide by this method and the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention."

15.2. Waste Streams Produced by the Method

15.2.1. Vials containing sample extracts. These vials are placed in the vial waste located in the GC/MS laboratory.

15.2.2. **Tubes containing sample extracts, for PCBs:** these are capped and placed in the PCB/flammable waste located the GC prep laboratory.

15.2.3. Samples, standards, and all extraction materials contaminated with high levels (>50ppm) of PCB's must be segregated into their own waste stream. PCB wastes are collected in one of three waste streams, solid PCB, liquid PCB and PCB vial waste. PCB containing samples are located through a LIMS query and disposed of as PCB containing.

15.2.4. **Extracted solid samples contaminated with methylene chloride/acetone or acetone/hexane:** These materials are disposed of in the solid waste and debris in a red container located in the Extractions Lab.

15.2.5. **Discarded samples:** These samples are collected in the solid debris drum.

17. MISCELLANEOUS

17.1. Modifications from Reference Method

17.1.1. Chapter 1 of SW-846 states the method blank must not contain any analyte of interest at, or above, the Method Detection Limit. This SOP states the Method Blank must not contain any analyte of interest at, or above, the reporting limit.

17.1.2. The extended hold time for PCBs can be applied to 8082 as per SW846 Update IV. State requirements should be consulted as applicable.

17.2. Tables

Table 1
Standard Analyte List and CAS Numbers

Compound	CAS #
Aroclor 1016	12674-11-2
Aroclor 1221	11104-28-2
Aroclor 1232	11141-16-5
Aroclor 1242	53469-21-9
Aroclor 1248	12672-29-6
Aroclor 1254	11097-69-1
Aroclor 1260	11096-82-5

TABLE 2
Suggested Instrumental Conditions for Methods 8082 and 8082A

Parameter	Recommended Conditions
Injection port temp	220°C
Detector temp	325°C
Temperature program	70°C for 0.5min, 30°C/min to 190°C, 2.5°C/min to 225, 18°C/min to 280°C, 3 min hold
Column 1	CLPesticide I, 30m, 0.53mm ID, 0.5µm
Column 2	CLPesticide II, 30m, 0.53 mm ID, 0.5µm
Injection	1-2 µL, -
Carrier gas	Hydrogen
Make up gas	Nitrogen
Y splitter	Glass, Restek or equivalent

Title: SOXHLET (TRADITIONAL) EXTRACTION OF ORGANIC COMPOUNDS FROM SOILS BASED ON METHOD SW846 3540C

[Method: SW846 3540C]

Facility Distribution No. _____ Distributed To:_____

The controlled copies of this SOP are the PDF copy that is posted to the laboratory's SOP Directory and, where applicable, the copy that is printed and placed in the General Chemistry SOP binder. Printed or electronic copies of this SOP that are distributed outside of the facility are considered uncontrolled.

1. SCOPE AND APPLICATION

1.1. This SOP describes procedures for preparation (extraction) of semivolatile organic analytes in soil, sediment, waste and wipe matrices for analysis by Gas Chromatography (GC) and Gas Chromatography/Mass Spectrometry (GC/MS) using Soxhlet Extraction. The procedures are based on SW846 series methodology and are applicable for measurements made to comply with the Resource Conservation and Recovery Act (RCRA) and for wastewater testing.

1.1.1. Extraction procedures for the following determinative methods are covered: 8081A, 8081B, 8082, 8082A, 8270C, 8270D, 8270E, 8015B, 8015C, and 8015D.

1.1.2. The extraction procedures herein may be appropriate for other determinative methods when appropriate spiking mixtures are used.

1.1.3. Where requirements of this SOP are not met, including, but not limited to, Quality Control (QC) samples (Method Blank (MB) and Laboratory Control Sample (LCS)) associated to sample analytes, holding time, and preservation, the laboratory will narrate potential bias in the case narrative of the final report.

2. SUMMARY OF METHOD

2.1. Soxhlet Extraction (Traditional)

2.1.1 A 30 g sample (10 g for Pesticides and PCBs) is mixed with anhydrous sodium sulfate until free flowing, or a 1 wipe sample is placed in an extraction thimble. They are extracted by refluxing with solvent.

2.2. Concentration

2.2.1 Procedures are presented for drying the extract and concentration of the extract to final volume for analysis.

3. DEFINITIONS

3.1. Definitions of terms and acronyms used in this SOP may be found in the glossary of the Eurofins TestAmerica Canton Quality Assurance Manual (QAM), current version.

4. INTERFERENCES

4.1. Method interferences may be caused by contaminants in solvents, reagents, glassware, and other processing apparatus. All of these materials must be routinely demonstrated to be free from interferences under conditions of the analysis by running laboratory method blanks as described in the Quality Control section. All

glassware is cleaned per SOP NC-QA-014, current version. Specific selection of reagents may be required to avoid introduction of contaminants.

4.2. Visual interferences or anomalies (such as foaming, emulsions, odor, etc.) must be documented.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual, the Facility Addendum to the Corporate EH&S Manual, and this document.

5.2. Eye protection that protects against splash, laboratory coat and appropriate gloves must be worn while samples, standards, solvents and reagents are being handled. Cut-resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have become contaminated must be removed and discarded; other gloves must be cleaned immediately.

5.3. The following analytes have been tentatively classified as known or suspected, human or mammalian carcinogens: benzo(a)anthracene, benzidine, 3,3'dichlorobenzindine, benzo(a)pyrene, alpha-BHC, beta-BHC, gamma-BHC, delta-BHC, dibenz(a,h)anthracene, N-nitrosodimethylamine, 4,4'-DDT, and polychlorinated biphenyl compounds. Primary standards of these toxic compounds must be prepared in the hood.

5.4. The following is a list of the materials used in this method, which have a serious or significant hazard rating. NOTE: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the Safety Data Sheet (SDS) for each of the materials listed in the table. A complete list of materials used in the method can be found in the Reagents and Standards section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material	Hazards	Exposure Limit (1)	Signs and symptoms of exposure
Methylene Chloride	Carcinogen Irritant	25 ppm-TWA 125 ppm-STEL	Causes irritation to respiratory tract. Has a strong narcotic effect with symptoms of mental confusion, light-headedness, fatigue, nausea, vomiting and headache. Causes irritation, redness and pain to the skin and eyes. Prolonged contact can cause burns. Liquid degreases the skin. May be absorbed through skin.
Acetone	Flammable	1000 ppm-TWA	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Hexane	Flammable Irritant	500 ppm-TWA	Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Vapors may cause irritation to the skin and eyes.
Note: Always add acid to water to prevent violent reactions.			
1 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.5. Exposure to hazardous chemicals must be maintained **as low as reasonably achievable.** All samples with stickers that read "Caution/Use Hood!" **must** be opened in the hood. Contact the EH&S Coordinator if this is not possible. Solvent and waste containers must be kept closed unless transfers are being made.

5.6. The preparation of standards and reagents and glassware cleaning procedures that involve solvents such as methylene chloride must be conducted in a fume hood with the sash closed as far as the operations will permit. If more than 500 mL of methylene chloride is spilled, evacuate the area until the area has been cleaned by EH&S.

5.7. All work must be stopped in the event of a known or potential compromise to the health and safety of a Eurofins TestAmerica Canton associate. The situation must be reported **immediately** to the EH&S Coordinator and the Laboratory Supervisor.

5.8. During Kuderna-Danish (KD) concentration, do not allow the extract to boil to dryness. The solvent vapors remaining in the KD apparatus may superheat and create an explosion or fire hazard. The KD apparatus and glass separatory funnels have ground glass joints that can become stuck. Technicians must use Kevlar or other cut/puncture-resistant gloves when separating stuck joints.

6. EQUIPMENT AND SUPPLIES

6.1. Glassware must be cleaned per Glassware Washing, SOP NC-QA-014.

6.2. Equipment and supplies for extraction procedures:

EQUIPMENT AND SUPPLIES	Sox	Conc
Graduated cylinder: 1 liter. (other sizes may be used as needed)		√
Methylene chloride collection tank for waste disposal	√	
Erlenmeyer flask: 250 mL (other sizes optional)		√
Solvent dispenser pump or 100 mL graduated cylinder	√	√
Round or flat bottom: 250 mL	√	
Boiling chips: contaminant free, approximately 10/40 mesh (Teflon® PTFE, carbide or equivalent)	√	√
Cooling condensers	√	
Heating mantle: rheostat controlled or equivalent	√	
Auto-timer for heating mantle	√	
Soxgriddle or equivalent	√	
Beakers: 450mL wide-mouth glass jars		√
Balance: >100 g capacity, accurate to ±1.00 g	√	√
Soxhlet extractor	√	
Cellulose and glass thimbles	√	
Kuderna-Danish (K-D) apparatus: 500 mL		√
Concentrator tube: 10 mL, attached to K-D with clips		√
Snyder column: three-ball macro		√
Water bath: heated, with concentric ring cover, capable of temperature control (± 5°C) up to 95°C. The bath must be		√

EQUIPMENT AND SUPPLIES	Sox	Conc
used in a hood or with a solvent recovery system.		
Vials: glass, 2 mL and 40 mL capacity with Teflon®-lined screw-cap		√
Clean wipes for wipe matrix method blanks and laboratory control samples		
Nitrogen blowdown apparatus		√
Nitrogen: reagent grade.		√
Culture Tubes: 10 mL, 16 x100 mm		√
Microliter pipette and/or syringe 1 mL	√	
Glass wool	√	
Glass funnel: 75 X 75 mm	√	√
Disposable pipettes, 5 ¾ in, and 9in.	√	√
Aluminum foil	√	√

7. REAGENTS AND STANDARDS

7.1. Reagents for Extraction Procedures

7.2. All reagents must be ACS reagent grade or better, unless otherwise specified.

REAGENTS	Sox	Conc
Sodium sulfate (Na_2SO_4), Granular, Anhydrous: Purify by heating at 800°C a minimum of one hour.	√	√
Magnesium sulfate	√	
Extraction Solvents (pesticide quality or equivalent): Methylene chloride, Methylene Chloride/acetone hexane/acetone,	√	√
Hexane/Acetone:, reagent grade: Used for cleaning glassware.	√	√

7.3. Standards

7.3.1. Stock Standards

7.3.1.1. Stock standards are purchased as certified solutions. S tock standards are stored according to manufacturer's instructions. All stock standards must be protected from light. Stock standard solutions must be replaced after one year (from the time of preparation, if prepared in house, or from the time the ampoule is opened, if purchased). Standards that are cold stored must be allowed to come to room temperature before use.

7.3.2. Surrogate Spiking Standards

7.3.2.1. Prepare or purchase surrogate spiking standards at the concentrations listed in Table 2. Surrogate spiking standards are purchased or prepared as dilutions of the stock standards.

Surrogate spiking solutions must be refrigerated and protected from light, or stored according to manufacturer's instructions. The standards must be replaced every six months at a minimum, or sooner if there is reason to believe that the standard has degraded or concentrated.

7.3.3. Matrix Spiking and Laboratory Control Spiking Standards

7.3.3.1. The same spiking solution is used for the matrix spike and the Laboratory Control Sample. Prepare MS/LCS spiking standards at the concentrations listed in Table 3. Spiking standards are purchased or prepared as dilutions of the stock standards.

7.3.3.2. Spiking solutions must be refrigerated and protected from light, or stored according to manufacturer's instructions. The standards must be replaced every six months at a minimum, or sooner if there is reason to believe that the standard has degraded or concentrated.

7.3.4. See SOP NC-QA-017 for additional information on Standards and Reagents.

8. SAMPLE COLLECTION PRESERVATION AND STORAGE

8.1. Samples are not chemically preserved.

8.2. Samples are stored at 4°C ± 2°C in glass containers with Teflon®-lined caps.

8.3. Holding Times

8.3.1. The holding time for solid and waste samples is 14 days from sampling to extraction.

8.3.2. Analysis of the extracts is completed within 40 days of extraction.

8.3.3. Unless otherwise specified by regulatory or client programs, the holding time for PCB samples is 1 year from sampling to extraction.

9. QUALITY CONTROL

9.1. Quality Control Batch

9.1.1. The batch is a set of up to 20 client samples and appropriate QC that are of the same matrix and are processed together using the same procedures and reagents. The batch must contain a method blank (MB), an LCS, and a matrix spike/matrix spike duplicate (MS/MSD). (In some cases, at client request, it may be appropriate to process a matrix spike and un-spiked sample duplicate in place of the MS/MSD). If clients designate specific samples for MS/MSD,

the batch may contain multiple MS/MSD pairs. See Policy QA-003 for further definition of the batch.

9.2. Method Blank (MB)

9.2.1. An MB consisting of all reagents added to the samples must be prepared and analyzed with each batch of samples. Surrogates are spiked into the MB at the same level as the samples. See Table 2 for the appropriate amount of surrogate to use for each analytical method. The MB is used to identify any background interference or contamination of the analytical system which may lead to the reporting of elevated concentration levels or false positive data.

9.2.2. For a solid MB, use approximately 30 g of sodium sulfate spiked with the surrogates. For PCB and Pesticides, use approximately 10 g ± 0.5 g of sodium sulfate. See Table 2 for the appropriate amount of surrogate to use for each analytical method. The MB goes through the entire analytical procedure.

9.2.3. For a wipe MB, use 1 clean wipe spiked with the surrogates. See Table 2 for the appropriate amount of surrogate to use for each analytical method. The MB goes through the entire analytical procedure.

9.3. Laboratory Control Sample (LCS)

9.3.1. LCSs are well-characterized laboratory-generated samples used to monitor the laboratory's day-to-day performance of routine analytical methods. The LCS, spiked with a group of target compounds representative of the method analytes, is used to monitor the accuracy of the analytical process, independent of matrix effects. Ongoing monitoring of the LCS results provides evidence that the laboratory is performing the method within accepted QC guidelines for accuracy and precision. The LCS goes through the entire analytical procedure.

9.3.2. The LCS is made up in the same way as the MB (see Sections 9.2.1 through 9.2.3), but spiked with the LCS standard and the surrogates. See Table 3 for the appropriate amount of spike to use for each analytical method.

9.4. Surrogates

9.4.1. Surrogates are organic compounds which are similar to the target analyte(s) in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.

9.4.2. Each applicable sample, MB, LCS, and MS/MSD is spiked with surrogate standards. Surrogate spike recoveries must be evaluated by determining whether the concentration (measured as percent recovery) falls within the required recovery limits of the applicable determinative method. See Table 2 for the appropriate amount of surrogate spike to use for each analytical method.

Company Confidential & Proprietary

9.5. Matrix Spike/Matrix Spike Duplicate (MS/MSD)

9.5.1. An MS is an environmental sample to which known concentrations of target analytes have been added. An MSD is a second spiked aliquot of the same sample, which is prepared and analyzed along with the sample and MS. See Table 3 for the appropriate amount of spike to use for each analytical method.

9.6. QC requirements can be found in the various associated analytical SOPs.

9.7. Control Limits

9.7.1. Control limits are established by the laboratory as described in SOP NC-QA-018.

9.7.2. Laboratory control limits are internally generated and updated periodically, unless method specified. Control limits are easily accessible via the LIMs.

9.8. Method Detection Limits (MDLs) and MDL Verifications

9.8.1. MDLs and MDL Verifications are established and performed by the laboratory as described in SOPs CA-Q-S-006.

9.8.2. MDLs are easily accessible via the LIMs.

9.9. Nonconformance and Corrective Action

9.9.1. Any deviations from QC procedures must be documented as a nonconformance with applicable cause and corrective action.

10. CALIBRATION AND STANDARDIZATION

10.1. On a weekly basis, measure the appropriate volumes of solvents into the appropriate sized glass culture tubes gravimetrically. The “standard” glass culture tubes are sealed, and the meniscus is noted by marking a line on the tubes. The glass culture tubes containing the sample final extracts are then compared against the “standard” glass culture tubes of the appropriate volume and solvent to ensure the volumes are consistent. (See Table 1 for final volumes)The bottle top dispenser is calibrated quarterly and must be within ±5% of the target volume with an RSD ≤ 1%.

10.2. All labware, pipettes, bottle top dispensers, and balances are calibrated according to SOPs NC-QA-004 and NC-QA-015.

11. PROCEDURE

11.1. Procedural Variations

11.1.1. Procedural variations are allowed only if deemed necessary in the professional judgment of QA, operations supervisor, or designee to

accommodate variation in sample matrix, chemistry, sample size, or other parameters. Any variation in procedure must be completely documented using a Nonconformance memo and approved by a supervisor. The Nonconformance memo will be filed in the project file. Procedural variations are not allowed for Ohio VAP projects.

11.2. Soxhlet

11.2.1. Remove surrogate and matrix spiking solutions from refrigerator if cold stored, and allow to warm to room temperature.

11.2.2. If sample can be mixed easily in the sample jar, mix thoroughly by stirring with a clean plastic or wooden spoon or spatula. If the sample cannot be easily mixed (i.e., clay samples or samples of various and very different particle sizes), use the spoon or spatula to select enough separate portions from locations within the jar to produce a representative sample. Analyst judgment is important in determining how many portions and which locations are used to produce a representative aliquot. If the sample is uniform clay, at least 3 portions should be selected from different locations in the sample jar, if particle sizes or materials indicate a very non-homogenous sample, selection should be made carefully to collect an aliquot that represents the relative percentages of the various particle sizes and types in the sample jar.

11.2.3. Do not decant the water layer from sediment samples. The entire sample is used. A higher weight of sample portion must be weighed for sediment samples to account for the dry weight correction (see 11.2.3). Record and document in the LIMS if a water layer was present in the sample.

11.2.4. If the sample cannot be prepared using a Soxhlet due to matrix issues, a waste dilution may be required. Refer to SOP NC-OP-043 for the waste dilution procedure.

11.2.5. Place approximately 200mL of solvent into a 250 mL flat bottom flask containing one or two clean boiling chips. Weigh 30g ± 0.5 g of sample into a thimble or in a jar, recording the weight to the nearest 0.01g in LIMS. For PCB or Pesticides Extraction, weigh approximately 10 g of sample ± 0.5 g. Sample weights less than 30g, but over 1g, may be used if the appropriate reporting limits can be met. For sediment samples that contain excessive moisture, weigh 50 g ±0.5 g. For wipe samples, the wipe is placed in an extraction thimble. For concrete samples, weigh 5 g of sample ± 0.5g.

Note: Waste samples with difficult matrices (such as caulk) are extracted at 1g.

Note: Alternate sample volumes can be used as long as a representative sample can be obtained and the reagent levels are adjusted to maintain the sample to reagent ration. All samples and standards must be processed similarly.

11.2.6. Prepare an MB, LCS, and MS/MSD for each batch as specified in Section 9 of this SOP, using sodium sulfate or a clean wipe as the matrix for the LCS and MB. The parent sample is used for the MS/MSD. The weight of sodium sulfate used must be approximately the weight of soil used for samples.

11.2.7. Add anhydrous sodium sulfate to each solid, sediment or waste sample and mix well. The mixture must have a free-flowing texture. If not, add more sodium sulfate. Add the sample/sodium sulfate mixture to a soxhlet extractor thimble, but do not pack the mixture tightly. The soxhlet extractor must drain freely for the duration of the extraction period. A glass wool plug below the sample in the soxhlet extractor is used for the extractions. Pesticides use specific silane treated glass wool.

11.2.8. Add the appropriate amount of surrogate and matrix spiking solution as indicated in Tables 2 and 3.

11.2.9. Attach the flask to the extractor and rinse the extractor with 20-30 mL of the appropriate solvent. Attach extractor to heating griddle and extract the sample for 16-24 hours at 4-6 cycles per hour. Check the system for leaks at the ground glass joints after it has warmed up.

Note: If a reduced quantity of sample is extracted, it is usually necessary to increase the amount of sodium sulfate added or increase the solvent boiling rate to properly set the cycling rate.

Solvents:

Semivolatile GC/MS and TPH	1:1 v/v Methylene Chloride / Acetone
8270 (MS) and TPH Concrete	Methylene Chloride only
PCB and Pesticides	1:1 v/v Hexane / Acetone
8082 Concrete	1:1 v/v Methylene Chloride/Acetone

11.2.10. Allow the extract to cool after the extraction is complete then disassemble by gently twisting the soxhlet from the flask.

11.2.11. The sample is now ready for the concentration step (Section 11.3).

11.2.12. Cap the samples with flask stopper and store at 4°C ± 2°C if the extract will not be concentrated immediately. Refer to Section 11.3 for concentration.

11.3. Concentration: According to the type of sample, different solvents and final volumes will be required. Refer to Table 1 for the appropriate final volumes and concentrations.

11.3.1. Kuderna-Danish (KD) Method:

11.3.1.1. Assemble a Kuderna-Danish concentrator by attaching a 10 mL concentrator tube (CT) to the 500 mL KD flask. Label the CT and

KD. Transfer the sample to the labeled K-D flask filtering the extracts through funnels filled with sodium sulfate. Rinse the sample flasks from the soxhlet setups with approximately 10 – 20 mL of methylene chloride Transfer the rinsate through the funnel and rinse the funnel with 20-30 mL of methylene chloride to complete the quantitative transfer.

11.3.1.2. Add one or two clean boiling chips to the KD flask and attach a three-ball Snyder Column. Add approximately 1 mL of clean methylene chloride to the top of the Snyder column. **Note:** It is important to wet with MeCl to ensure that the balls in the Snyder column do not stick, and the column will work properly.

11.3.1.3. Place the KD apparatus on a water bath (90-98^{o}C) so the tip of the concentrator tube is submerged. The water level must not reach the joint between the concentrator and the KD flask. At the proper rate of distillation, the balls will actively chatter; but the chambers should not flood.

11.3.1.4. Concentrate to 15-20 mL. If the determinative method requires a solvent exchange, add the appropriate exchange solvent to the top of the Snyder Column, and then continue the water bath concentration back down to 5-8 mL. Refer to Table 1 for details of exchange solvents and final volumes. The Snyder column may be insulated if necessary to maintain the correct rate of distillation.

Note: It is very important not to concentrate to dryness as analytes will be lost.

11.3.1.5. Remove the KD apparatus from the water bath and allow to cool for a minimum of 10 minutes. If the level of the extract is above the level of the CT joint, continue to distill the solvent as necessary. Again, allow the KD flask to cool for a minimum of 10 minutes.

11.4. Nitrogen Evaporation to Final Concentration

11.4.1. Transfer the CT to the evaporation apparatus.

11.4.2. Place the tube in a warm water bath that is at least 5^{o}C below the boiling temperature of the solvent being evaporated and evaporate the solvent using a gentle stream of nitrogen. The nitrogen flow will form a slight depression on the surface of the solvent, but must not create splattering of the extract.

Boiling points of commonly used solvents are:

Methylene chloride	40^{o}C
Acetone	56^{o}C
Hexane	69^{o}C
Acetonitrile	82^{o}C

Note: It is very important not to concentrate to dryness as analytes will be lost.

11.4.3. Refer to Table 1 to determine the final volume needed for a specific test method. Evaporate to slightly less than the required final volume.

11.4.4. Rinse the CT and quantitatively transfer the extract with the rinsate to the appropriate final container, and dilute to the appropriate final volume using the "standard" glass vial noted in Section 10.1. Cap the sample and affix the appropriate label. The sample is now ready for analysis.

Note: The final concentration and volume measurement steps are critical. Use care when concentrating and make certain that the final volume measurement is accurate.

11.5. Analytical Documentation

11.5.1. Record all analytical information in LIMS, including any corrective actions or modifications to the method.

11.5.2. Record all standards and reagents in the LIMS Reagents module. All standards and reagents are assigned a unique number for identification.

11.5.3. Record sample and associated QC information into LIMs. Level I and Level II technical reviews are performed in LIMS.

12. DATA ANALYSIS AND CALCULATIONS

12.1. Not applicable

13. METHOD PERFORMANCE

13.1. Initial Demonstration

13.1.1. Each analyst must make an initial demonstration of capability (IDOC) for each individual method. This requires analysis of four QC check samples. The QC check sample is a well-characterized laboratory generated sample used to monitor method performance, which must contain all of the analytes of interest. The spiking level must be equivalent to a mid-level calibration. (For certain tests, more than one set of QC check samples may be necessary in order to demonstrate capability for the full analyte list.)

13.1.2. Four aliquots of the QC check sample are analyzed using the same procedures used to analyze samples, including sample preparation.

13.1.3. Calculations and acceptance criteria for the QC check samples are given in the determinative SOPs. See SOPs NC-GC-038, NC-MS-018, NC-MS-003, and NC-GC-007 for detailed information on the determinative methods.

Company Confidential & Proprietary

13.1.4. Method validation information (where applicable) in the form of analyst demonstrations of capabilities is maintained for this method in the analyst's training files

13.2. Training Qualification

13.2.1. The Group/Team Leader has the responsibility to ensure that this procedure is performed by an analyst who has been properly trained in its use and has the required experience.

14. POLLUTION PREVENTION

14.1. It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage, and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention".

15. WASTE MANAGEMENT

15.1. All waste will be disposed of in accordance with Federal, State, and local laws and regulations. Where reasonably feasible, technological changes have been implemented to minimize the potential for pollution of the environment. Employees will abide by this method the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention."

15.2. The following waste streams are produced when this method is carried out.

15.2.1. Used sodium sulfate and glass wool or filter paper contaminated with methylene chloride/acetone or acetone/hexane from the extract drying step. These materials are disposed of in the solid waste and debris in a red container located in the Extractions Lab.

15.2.2. **Assorted flammable solvent waste from various rinses**: These wastes are put into the halogenated/non-halogenated 25 gallon solvent waste container located under the fume hood in extractions.

15.2.3. **Methylene chloride waste from various rinses:** These wastes are disposed of in the liquid-liquid separation unit.

15.2.4. **Hexane-Hexane waste:** These samples are to be disposed in the flammable waste.

15.2.5. **Waste Hexane in vials:** These vials are placed in the vial waste located in the GC prep laboratory.

15.2.6. **Waste Methylene Chloride sample vials**: These vials are placed in the vial waste located in the GC prep laboratory.

15.2.7. **Extracted solid samples contaminated with methylene chloride/acetone or acetone/hexane:** These materials are disposed of in the solid waste and debris in a red container located in the Extractions Lab.

15.2.8. Samples, standards, and all extraction materials contaminated with high levels (>50ppm) of PCBs must be segregated into their own waste stream. PCB wastes are collected in one of three waste streams, solid PCB, liquid PCB, and PCB vial waste.

15.2.9. Solvent Recovery System Waste: Methylene Chloride waste from the Solvent Recovery System is collected and disposed of in the liquid-liquid separation unit. Acetone/Methylene Chloride waste from this system is disposed of in the flammable waste containers located in the laboratory.

17. MISCELLANEOUS

17.1. Modifications from Reference method

17.1.1. Some surrogate spiking concentrations are modified from those recommended in SW-846, in order to make the concentrations more consistent with the calibration levels in the determinative methods.

17.1.2. Sodium sulfate is heated for 1 hour at 800°C to purify. The reference method lists a minimum of 4 hours at 400°C.

17.2. Tables

Company Confidential & Proprietary

TABLE 1
Final Volumes and Exchange Solvents

Type	Exchange Solvent for Analysis*	Final Volume for Analysis in mL
Semivolatiles	N/A	2.0 mL
PCB	Approximately 36 mL Hexane	2.0 mL
Pesticides	Approximately 18 mL Hexane	2.0 mL
TPH	N/A	5.0

Note: *PCBs and Pesticides only need the solvent exchange step when they are extracted in methylene chloride / acetone. If they are extracted in hexane / acetone, no solvent exchange is necessary.*

Note: *Different final volumes may be necessary to meet special client reporting limit requirements.*

TABLE 2
Surrogate Spiking Solutions

Analyte Group	Surrogate Spike Solution ID	Volume (mL)
BNA	20 ppm BNA	1.0
PEST	0.2 ppm DCB/TCX	1.0
TPH	o-Terphenyl	1.0
PCB	0.2 ppm DCB/TCX	1.0

TABLE 3
Matrix Spike and LCS Solutions

Analyte Group	Matrix Spike Solution ID	Volume (mL)
BNA	20 ppm BNA All-Analyte Spike	1.0
PEST	Pest NPDES Spike	1.0
PCB	10 ppm PCB Spike	1.0
TPH	Diesel Spike	1.0

1. SCOPE AND APPLICATION

1.1. These disaggregation, mixing and particle size reduction techniques are applicable to a wide range soil, sediment, tissue, water, and waste samples. Care must be taken to match the appropriate technique with the matrix, target analytes and quality objectives.

1.2. This document accurately reflects current laboratory Standard Operating Procedures (SOP) as of the date above. All facility SOPs are maintained and updated as necessary.

Note: If foreign or quarantined solids are received, refer to SOP NC-SC-019 Canton Foreign Soils, current revision, and contact your Environmental Health and Safety Coordinator for proper handling instructions

2. SUMMARY OF METHOD

2.1. Air-Dried Soil Processing: The sample is air dried at room temperature and disaggregated to break clumps into a fine powder to facilitate obtaining a representative sub-sample and improving analyte extraction efficiency.

2.2. Soil Fractionation for Lead: Applicable to lead impacted soil and designed to distinguish the lead in the fine soil fraction from the coarse soil fraction.

2.3. Incremental Sample Wet Mixing Process: Applicable to mixing incremental samples into a single composite. These samples are NOT air dried, but rather water is added to facilitate mixing in a heavy-duty mixer.

3. DEFINITIONS

3.1. Refer to the glossary in the Eurofins TestAmerica Canton QA Manual, current version.

3.2. Mix: To thoroughly blend the sample and reduce the analyte concentration differences between different parts of the overall sample. It is most effective when the particle size and density differences within the sample are small.

3.3. Incremental Sampling Methodology: A structured composite sampling and processing protocol that reduces data variability and provides a reasonably unbiased estimate of the mean contaminant concentrations in an area/volume of soil targeted for sampling. ISM provides representative samples of specific soil areas/volumes defined as decision units (DUs) by collecting numerous increments of soil (typically 30-100 increments) that are combined, processed, and subsampled according to specific protocols.

Company Confidential & Proprietary

3.4. Grinding: A generic term for soil disaggregation or milling (ITRC Guidance Appendix E). The term grinding does not in itself represent any specific process.

3.5. Disaggregation: The act of breaking the soil clumps into individual small particles but keeping the small pebbles and hard crystalline particles intact (ITRC Guidance Appendix E).

3.6. Milling: Complete particle size reduction of all soil components including hard crystalline materials to a defined maximum particle size (e.g. <250 µm or <75 µm) (ITRC Guidance Appendix E).

3.7. Sample: For laboratory technicians, the sample is all the material delivered to the laboratory in a container collected by the field crew.

3.8. Subsample: The small representative amount removed from a field sample that selected for final analysis. Also referred to in some SOPs as “the aliquot”.

4. INTERFERENCES

4.1. Method interferences may be caused by contaminants in solvents, reagents, glassware, and other processing apparatus that lead to discrete artifacts. All of these materials must be routinely demonstrated to be free from interferences under conditions of the analysis by running laboratory method blanks as described in the Quality Control section of each analytical SOP. Specific selection of reagents may be required to avoid introduction of contaminants (i.e. samples being analyzed for VOCs should generally not come into contact with equipment that has been solvent-rinsed with acetone or methylene chloride).

4.2. Metallic components of particle size reduction equipment can contribute some metal content to the solid samples. Hence carbon steel components are usually preferable to stainless steel when necessary to minimize contamination from chromium, nickel and molybdenum. Some contamination from iron is common.

4.3. Particle size reduction equipment blanks should be generated before use. The type of blank generated may vary for each piece of equipment, and may be solid or aqueous in nature.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the NDSC EH&S Manual, the Facility Addendum to the NDSC EH&S Manual, and this document.

5.2. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut-resistant gloves must be worn while doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

Company Confidential & Proprietary

5.3. Exposure to chemicals must be maintained **as low as reasonably achievable**; therefore, unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation where possible. All samples with stickers that read "Caution/Use Hood!" **must** be opened in the hood. Contact the EH&S Coordinator if this is not possible. Solvent and waste containers will be kept closed unless transfers are being made.

5.4. The following is a list of the materials used in this method, which have a serious or significant hazard rating. NOTE: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the Reagents and Standards section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material	Hazards	Exposure Limit (1)	Signs and symptoms of exposure
Acetone	Flammable	1000 ppm-TWA	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Methanol	Flammable Poison Irritant	200 ppm-TWA	A slight irritant to the mucous membranes. Toxic effects exerted upon nervous system, particularly the optic nerve. Overexposure may include headache, drowsiness and dizziness. Methanol is a defatting agent and may cause skin to become dry and cracked. Skin absorption can occur: symptoms may be parallel to inhalation exposure. Irritant to the eyes.
Hydrochloric acid	Corrosive Poison	5ppm-Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failure, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Note: Always add acid to water to prevent violent reactions.			
1 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.5. All work must be stopped in the event of a known or potential compromise to the health and safety of a Eurofins TestAmerica associate. The situation must be reported **immediately** to the EH&S Coordinator and the Laboratory Supervisor.

5.6. When operating the electric chopper or grinder, be sure to keep all aqueous liquids clear to prevent the risk of electrical shock from any spills.

5.7. Avoid inhalation of sample dust. Work in a ventilation hood when necessary to avoid accidental dust inhalation. Wear a dust mask or respirator if the ventilation hood does not provide sufficient dust protection. The Environmental Health and Safety Coordinator must approve any and all use of dust masks and/or respirators.

5.8. If there is any malfunction in the equipment de-energize and tag out.

5.9. All noise levels are below OSHA limits.

5.10. Training: Only trained personnel are permitted to use the equipment mentioned in this document. A list of trained personnel will be maintained with EH&S and QA.

6. EQUIPMENT AND SUPPLIES

6.1. Drying tray, plastic or aluminum

6.1.1. Half cake sheet pan, Pactiv #614255, or equivalent

6.1.2. Quarter sheet cake pan, Pactiv #604245, or equivalent

6.2. Butcher Paper

6.3. Plastic wrap

6.4. Mortar and pestle

6.5. Automated mortar grinder

6.6. Food chopper, Black and Decker Handi chopper, or DeLonghi mini food processor, or equivalent

6.7. Coffee grinder, KitchenAid BCG100 or equivalent

6.8. Automated soil disaggregator

6.9. Wooden spatula: 6 in.

6.10. Stainless steel sieves: 1 mm, #10, #20, #60, #100, ¼ inch, other sizes by request with advanced notice

6.11. Electrolux Assistant 8 qt mixer, with dough hook or equivalent

6.12. Large cookie scoop with hand actuated ejector blade

6.13. Small cookie scoop with hand actuated ejector blade

6.14. Fluoropolymer scoop, not commercially available

6.14.1. Construct by fastening the bottom half of a fluoropolymer bottle to a wooden handle with stainless steel screws.

6.15. Stainless steel pot with cover, Bain-Marie 6 qt. or equivalent

6.16. Wooden spoon, 12” long

Picture of labware for multi-increment sample wet mixing process (Section 11.3.2.5): large scoop, small scoop, wooden spoon, fluoropolymer scoop, stainless steel pot/cover

6.17. Jaw crusher, Sepor Model 150 or equivalent

6.18. Freezer for sample storage.

6.19. 8 oz. Glass jars with lids

6.20. Top loading balance capable of weighing 100 g ±0.2 g.

6.21. Aluminum foil

7. REAGENTS AND STANDARDS

7.1. Deionized water: Reagent water must be produced by a Millipore DI system or equivalent. Reagent water must be free of the analytes of interest as demonstrated through the analysis of preparation blanks.

7.2. Methanol: VOC grade

7.3. Acetone: Pesticide grade

8. SAMPLE COLLECTION, PRESERVATION, AND STORAGE

8.1. Not applicable to this procedure. Sample collection, preservation, and storage are dependent on the requested test method and analytes.

9. QUALITY CONTROL

9.1. Equipment processing blanks might be applicable for some particle size reduction or selection techniques. There is no single blank matrix that is suitable for all analytes, equipment or processes. The blank matrix should be chosen by the client/data user based on the advantages and limitations described below in Section 9. If no blank

matrix is selected by the client, reagent water should be used as the default when possible as noted in Section 9.2.

9.2. Reagent water (or organic solvents) may be used to rinse the equipment surfaces. This liquid is then analyzed for the target analytes. This process is good at monitoring residue on equipment surfaces from previously processed samples. It does not evaluate the potential contribution of the equipment surface material to a solid sample. Sand may be run through processing equipment and then analyzed to monitor for both sample carryover residue and contamination from equipment surface erosion. This process is most applicable for organic analytes. Sand always contains metals. These metals concentrations might be too high for suitable blank demonstrations. Also, the sand material is frequently more abrasive than soil and can over-estimate sample contamination due to erosion of the equipment surfaces.

9.3. Teflon boiling chips can be suitable to monitor the cleanliness of processing equipment surfaces. This option is between reagent water and sand regarding abrasion of the equipment surfaces. This material is generally non-detect at parts per billion concentrations for most organic and inorganic analytes. The Teflon material does not mimic the behavior of soil in the subsequent sample extraction or digestion procedures.

9.4. As an alternative to or in addition to equipment blanks, half of a field sample may be reprocessed with the goal of evaluating differing analyte concentrations between the single and double processed sample aliquots. The occurrence of significantly elevated analyte concentrations in the double processed sample can be a good indication of carryover or contamination due to equipment surface erosion. This is most applicable for monitoring metals contamination in soil grinders.

10. CALIBRATION AND STANDARDIZATION

10.1. Not applicable to this procedure.

11. PROCEDURE

11.1. One-time procedural variations are allowed only if deemed necessary in the professional judgment of QA, operations supervisor, or designee to accommodate variation in sample matrix, chemistry, sample size, or other parameters. Any variation in procedure shall be completely documented using a Nonconformance Memo.

11.2. Any unauthorized deviations from this procedure must also be documented as a nonconformance with a cause and corrective action described.

11.3. Sample Preparation

11.3.1. The following sections describe a variety of procedures. The client/data user must select the procedure that is most appropriate for the sample matrix, analytes, and quality objectives. The selection of the procedure(s)

can be made by the client in consultation with the appropriate laboratory representatives during project planning. There is no single default procedure that can be used in the absence of client selection.

11.3.2. Solid Sample Mixing and Particle Size Reduction Procedures

11.3.2.1. In jar mixing

11.3.2.1.1. The flowable sample is thoroughly stirred in the sample jar using a wooden blade.

11.3.2.2. Horizontal surface mixing

11.3.2.2.1. The sample is transferred to an aluminum tray or onto a sheet of paper and mixed with a wood blade.

11.3.2.3. Mortar and pestle

11.3.2.3.1. A mortar and pestle can be used for samples in the 1 to 8 mm particle size. The final reduced size is between 5 um and 8 mm. This process can be used for wet or dry, organic or inorganic substances.

11.3.2.3.2. Fill the mortar about 1/3 with sample. Grind and mix the sample with the pestle. Transfer the processed sample to a separate container, and repeat the grind-and-mix step with additional sample aliquots as needed.

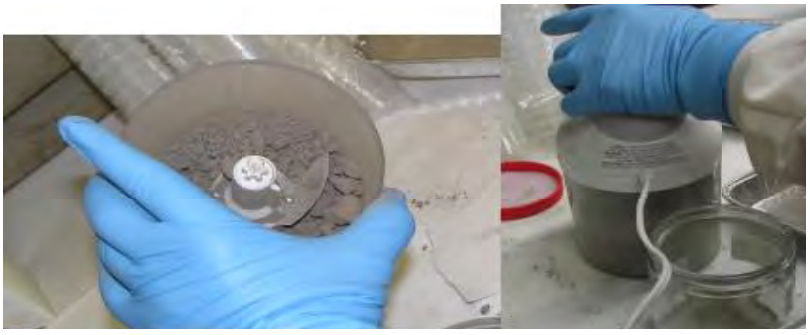
11.3.2.3.3. An automated mortar grinder may be appropriate for larger samples. Set the automated mortar grinder to the desired size and allow to run until the sample has been completely ground. If the grinder is not equipped with an automated scraper/agitator, the sample may be mixed by hand. Be sure that the grinder has stopped moving completely before opening the lid.

11.3.2.4. Dry mixing (incremental sampling methodology support)

11.3.2.4.1. Air dry, disaggregate, sieve, mix

11.3.2.4.1.1. Line a standard aluminum tray with a disposable aluminum tray ($^1/_2$ or $^1/_4$ sheet depending on sample size). If aluminum is a metal of interest line the tray with butcher paper. Do not use butcher paper when TOCs are of interest.

11.3.2.4.1.2. Remove large rocks and vegetation unless client indicates otherwise. Do not decant the free water. Mix the sample and spread the entire sample in a thin layer in the tray. If necessary to perform a pre-dried total solids analysis, remove approximately 10 g. If the samples require ISM processing, an appropriate subsampling procedure should be followed, as described in the subsampling SOP.



Note: it is not recommended to remove any portion of an ISM sample prior to drying and disaggregation. Any such removal from an ISM sample is considered a deviation and should be approved by the client.

11.3.2.4.1.3. Place the tray in the ventilated drying rack for up to five days at room temperature.

11.3.2.4.1.4. Periodically, stir the sample to expose moist sample to the air.

11.3.2.4.1.5. The dried sample must be crushable, and not prone to sticking together. Typically this means that sediment samples will be less than 30% moisture content and soil samples less than 15% moisture content. However, it is not necessary to do a percent moisture analysis.

11.3.2.4.1.6. Disaggregate the dried sample to break up the dried sample clumps with a bladed chopper or equivalent, but do not grind the small pebbles into powder.

11.3.2.4.1.7. If the volume capacity of the disaggregation equipment is large enough, transfer the whole sample to the disaggregator. If sample volume is too large, disaggregate the sample in sub-aliquots.

11.3.2.4.1.8. Pass the sample through a sieve to remove small pebbles and organic materials. Project specific guidelines will determine the sieve opening size. Typically, a #10 sieve is used for soils.

11.3.2.4.1.9. Combine all disaggregated sub-aliquots, and mix thoroughly by stirring, shaking or tumbling.

11.3.2.4.2. Air dry, disaggregate, mix

11.3.2.4.2.1. When the project objectives dictate that all small and medium sized materials be included in the final sample, use the procedure described in Section 11.3.2.4.1, but skip the sieving step in Section 11.3.2.4.1.8.

11.3.2.4.2.2. Collecting a representative subaliquot is more difficult when the sample has a variety of particle sizes. Refer to the subsampling SOP for recommended procedures. The one dimensional slabcake process is particularly applicable to dry, flowable samples with a wide range of particle sizes.

11.3.2.4.3. Other

11.3.2.4.3.1. Various permutations of soil disaggregation and sieving are possible depending on the needs of the project and can be accommodated but must be clearly defined in consultation with the client. These variations can include different sieve sizes and changing the order so that sieving is done prior to disaggregation. This would most likely be done to exclude a particular size of organic or rocky material.

11.3.2.5. Wet mixing (incremental sampling methodology support)

11.3.2.5.1. Weigh 100.0 +/- 0.2 g of each ¼ acre sub-sample. Stir the sample prior to and during the transfer from the original container to the weighing container. Record the weight to two decimal places.

11.3.2.5.1.1. If there are fewer than 40 sub-samples, increase the weight of sample proportionally. Calculate the new target weight as follows: target weight = 4000g/# sub-samples.

11.3.2.5.1.2. Exclude rocks, organic matter, and other debris from the weighed sub-sample by sieving through a ¼ inch sieve prior to weighing when such material is present.

11.3.2.5.1.3. The sieve may also be used to break up clay chunks. Sieving may be done either before or after weighing for this purpose. Use only when needed. Hard dry soil agglomerates should be broken up by hand crushing or chopping with a food chopper.

11.3.2.5.1.4. If a sub-sample is over ½ gravel, expand the maximum particle size from ¼ inch to 1.8 inches.

11.3.2.5.2. Transfer the weighed (and sieved as needed) sub-sample aliquot to a stainless steel pot used to collect all weighed aliquots for that composite sample. The total mass of the composite sample will be at least 4 kg.

11.3.2.5.3. Repeat Section 11.3.2.5.1 until all sub-samples have been weighed and transferred to the compositing pot.

11.3.2.5.4. Assemble the heavy-duty mixer with mixing hook. The mixing hook must be inserted high in the mounting bracket to avoid dragging on the bottom of the bowl and allow small stones to pass under the hook. Transfer the entire composite sample from the covered stainless steel pot to the stainless mixing bowl.

11.3.2.5.5. Turn on mixer. Add reagent water to ensure complete mixing of the sample. The mixed sample will have uniformly distributed water, look visually homogeneous, and have the consistency of a thick paste. Do not add so much water as to form runny slurry. Use a wooden spoon to assist the mixing process by scraping mud from the sides and directing it to the center. The picture below shows the proper consistency. Mix for three minutes after the proper consistency has been achieved.

Company Confidential & Proprietary

11.3.2.5.6. Record the volume of reagent water added and the total mixing time.

11.3.2.5.7. Scrape the mud from the wooden spoon and mixing hook.

11.3.2.5.8. Split the composite sample between 5-15 250 mL jars, depending on project requirements.

11.3.2.5.9. Use the large scoop to dispense the equal aliquots of the composite sample--one aliquot into each of 8 oz. jars. Repeat the process if there is sufficient sample for a complete set of large scoop aliquots (per Section 11.3.2.5.8).

11.3.2.5.10. Once the volume of wet composite sample in the bowl is less than the determined set of large scoops, switch to aliquoting with the small scoop. Dispense an equal amount of small scoops--one into each 8 oz. jar.

11.3.2.5.11. Use the fluoropolymer scoop to scrape inside the bowl, and dispense this part of the sample with the small scoop. If

there is insufficient sample to use full scoops, the use of replicate partial scoops is acceptable.

11.3.2.5.12. When aliquoting is complete, the composite sample has been evenly distributed among the 8 oz. jars. Note: Multiple jars are used for various analyses, quality control, and archive purposes.

11.3.2.5.13. Mix the contents of each 250 mL jar and remove about 10 g from each of the first three jars for three total solids (percent moisture) analyses. The relative percent difference (RPD) between the first two must not exceed 8%.

11.3.2.5.13.1. If the RPD exceeds 8%, repeat the total solids analysis on two fresh aliquots from the first two jars.

11.3.2.5.13.2. If the RPD still exceeds 8%, repeat the mixing process in Sections 11.3.2.5.1 to 11.3.2.5.12

11.3.2.5.14. Wipe the top of the jar to remove excess sample and install the cap. Transport all sample containers to Sample Receiving.

11.3.2.5.15. Discard the wooden spoon and spatulas. Wash the mixer bowl, hook and scoops using soap and water. Rinse with tap and reagent water.

11.3.2.6. Soil fractionation for lead analysis

11.3.2.6.1. Add sample ID label to outside of a disposable aluminum ($^1/_2$ or $^1/_4$ sheet depending on sample size). Line with butcher paper if aluminum is also an analyte of interest.

11.3.2.6.2. Transfer the soil sample to a tray. Remove large rocks and vegetation. Spreading the sample in a thin layer speeds drying and reduces the formation of hard clay chunks.

11.3.2.6.3. Place the tray in the ventilated drying rack for up to five days.

11.3.2.6.4. Periodically, stir the sample if needed to expose moist sample to the air. The butcher paper may also be changed, if it has become damp.

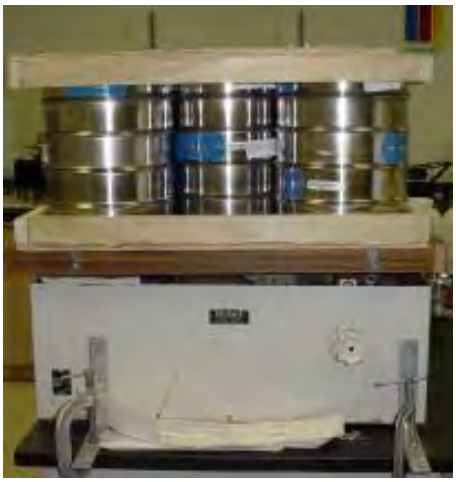
11.3.2.6.5. Samples with high clay content tend to form large, hard clay aggregates. To reduce the formation of these hard “bricks”, use the bottom of a clean disposable beaker to gently crush the semi-dried sample before drying is complete.

11.3.2.6.6. Allow the sample to dry until crumbly.

11.3.2.6.7. Assemble 8-inch sieve stack. The order from the bottom of the stack is collection pan, #60 sieve, and #10 sieve. Transfer sample ID label from drying pan to sieve stack.

Note: Project-specific sieve size requirements may vary from the reference method. These will be noted in LIMS, both in the project and in the method or login notes. #100 (150um) sieves are commonly used in place of #60 sieves. The smallest sieve size should be the closest to the collection pan, with the next size up above it.

11.3.2.6.8. If significant amounts of clay are present, aggregates may be broken by pressing gently with a hand-operated mortar and pestle. Note that only this gentle crushing is permitted by the reference method. Samples that are being analyzed as soil fractions for lead should not be subjected to aggressive disaggregation such as the use of a soil disaggregator or coffee grinder.



11.3.2.6.9. Transfer dried soil to the #10 sieve at the top of the sieve stack. If fine particulates are present, use sufficient ventilation to prevent the analyst from inhaling the dust. Install sieve cover.

11.3.2.6.1. Place the sieve stack on the shaker table and secure. Run the shaker for one hour. Stop the shaker and remove the lid for each sample to check on the progress of sieving. Shake the samples by hand (in a different direction than the shaker table has traveled). If any sample passes through the sieve at this point, place the sieve stack(s) back on the shaker and shake for up to one additional hour.

11.3.2.6.2. Do not extend shaking beyond two hours without conferring with the client.

11.3.2.6.3. Record the weights of the three fractions--large (did not pass through the #10 sieve), coarse (passed through #10 sieve, but not the #60 sieve), and fine (passed through both #10 and #60 sieves). If different sieve sizes have been used, record the sizes on the bench sheet.

11.3.2.6.4. To weigh each fraction, place the corresponding sieve or pan on the balance, press “Tare”, transfer the fraction, and place sieve or pan back on the balance. The weight of the fraction will read as a negative value.

11.3.2.6.5. Discard the large fraction. Mix the fine fraction. Remove approximately 10g for total solids analysis. If required, perform splitting and/or subsampling in accordance with ISM procedures. See the subsampling SOP for further information.

11.3.2.6.6. If the coarse fraction is to be analyzed separately, mix the coarse fraction and remove approximately 10g for total solids analysis. The coarse fraction should be ground in a mortar and pestle (Section 11.3.2.3) prior to removing the aliquot for metals digestion.

11.3.2.6.7. The combination of coarse and fine fractions is defined as the “total”. If the “total” is to be measured, weigh 1/10 of the coarse fraction and 1/10 of the fine fraction. Combine, mix, and remove approximately 10g for total solids analysis.

11.3.2.6.8. Bottle coarse, fine, and “total”(if needed) fractions for metals analysis.

11.3.2.6.9. For Michigan samples, the “total” result is calculated from a weighted average of the results from the fine and coarse fractions.

Total Lead = [(A x Wf) + (B x Wc)] / (Wf + Wc)

Where:

A = Concentration of Lead (mg/Kg dry) in fine fraction

B = Concentration of Lead (mg/Kg dry) in coarse fraction

Wf = Total weight of fine fraction

Wc = Total weight of coarse fraction

11.3.2.6.10. Wash the sieves with soap, tap water, and deionized water. Dislodge objects from the screen with a green scratch pad, wooden tongue blade or small screwdriver, as necessary. Dry sieves in a low-heat oven or air-dry at ambient temperature over night, depending how soon they will be needed.

Company Confidential & Proprietary

11.4. Sample Analysis

11.4.1. Not applicable to this procedure.

11.5. Analytical Documentation

11.5.1. Record all analytical information in LIMS, including any corrective actions or modifications to the method.

11.5.2. Record all standards and reagents in the LIMS Reagents module. All standards and reagents are assigned a unique number for identification.

12. DATA ANALYSIS AND CALCULATIONS

12.1. Not applicable to this procedure.

13. METHOD PERFORMANCE

13.1. The Group/Team Leader has the responsibility to ensure this procedure is performed by an associate who has been properly trained in its use and has the required experience.

14. POLLUTION PREVENTION

14.1. It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage, and reagent stability). Employees must abide by the policies in Section 13 of the NDSC EH&S Manual Document No. CW-E-M-001 for "Waste management and Pollution Prevention".

15. WASTE MANAGEMENT

15.1. All waste will be disposed of in accordance with Federal, State and Local regulations. Where reasonably feasible, technological changes have been implemented to minimize the potential for pollution of the environment. Employees will abide by this method and the policies in Section 13 of the NDSC EH&S Manual Document No. CW-E-M-001 for "Waste Management and Pollution Prevention".

15.2. Waste Streams Produced by the Method

15.2.1. Used wood spatulas, aluminum sheets, butcher paper; discard in solid waste.

15.2.2. Dry ice is to be melted in the sink.

15.2.3. Acetone is to be disposed of in an appropriately labeled flammable waste barrel.

15.3. Laboratory personnel assigned to perform hazardous waste disposal procedures must have a working knowledge of the established procedures and practices of Eurofins TestAmerica. They must have training on the hazardous waste disposal practices upon initial assignment to these tasks, followed by annual refresher training.

1. SCOPE AND APPLICATION

1.1. These mixing, subsampling, and splitting techniques are applicable to a wide range of soil, sediment, tissue, water, and waste samples. Care must be taken to match the appropriate technique with the matrix, target analytes and quality objectives.

1.2. The goal of all mixing, subsampling, and splitting techniques is to obtain representative splits or subsamples for preparation and analysis. Particle size reduction and processing can be beneficial in obtaining representative subsamples and specific processes for particle size reduction and processing can be found in the soil processing SOP (NC-OP-044) and non-soil processing SOP (NC-OP-045).

1.3. This document accurately reflects current laboratory Standard Operating Procedures (SOP) as of the date above. All facility SOPs are maintained and updated as necessary.

NOTE: If foreign or quarantined solids are received, refer to SOP NC-SC-019 Canton Foreign Soils, current revision, and contact your Environmental Health and Safety Coordinator for proper handling instructions.

2. SUMMARY OF METHOD

2.1. All samples should be mixed and subsampled appropriately for the test and analytes of interest.

2.2. Solid sample mixing procedures include in-jar mixing, horizontal surface mixing, and mortar and pestle.

2.3. Solid sample subsampling procedures include alternate scoop, one-dimensional slabcake, two-dimensional slabcake, and cone and quarter methods.

2.4. Liquid sample subsampling procedures include centrifuge, pipettes, coliwasa devices, and multiphase procedures.

3. DEFINITIONS

3.1. Refer to the glossary in the laboratory QA Manual, current version.

3.2. Mix: To thoroughly blend the sample and reduce the analyte concentration differences between different parts of the overall sample. It is most effective when the particle size and density differences within the sample are small.

3.3. Incremental Sampling Methodology: A structured composite sampling and processing protocol that reduces data variability and provides a reasonably unbiased estimate of the mean contaminant concentrations in an area/volume of soil targeted for sampling. ISM provides representative samples of specific soil areas/volumes defined as decision units

Company Confidential & Proprietary

(DUs) by collecting numerous increments of soil (typically 30-100 increments) that are combined, processed, and subsampled according to specific protocols.

3.4. Grinding: A generic term for soil disaggregation or milling.

3.5. Disaggregation: The act of breaking the soil clumps into individual small particles but keeping the small pebbles and hard crystalline particles intact.

3.6. Milling: Complete particle size reduction of all soil components including hard crystalline materials to a defined maximum particle size (e.g. <250 µm or <75 µm).

3.7. Sample: For laboratory technicians, the sample is all the material delivered to the laboratory in a container collected by the field crew.

3.8. Subsample: The small representative amount removed from a field sample selected for final analysis. This is also referred to in some SOPs as the aliquot.

3.9. Representative subsample: A subsample taken in such a way that each particle had an equal chance of being selected. The most representative subsample is one that most closely resembles the true value of the material sampled or contains the least amount of error.

4. INTERFERENCES

4.1. Method interferences may be caused by contaminants in solvents, reagents, glassware, and other processing apparatus that lead to discrete artifacts. All of these materials must be routinely demonstrated to be free from interferences under conditions of the analysis by running laboratory method blanks as described in the Quality Control section of each analytical SOP. Specific selection of reagents may be required to avoid introduction of contaminants.

4.2. Metallic components of particle size reduction equipment can contribute some metal content to the solid samples. Hence carbon steel components are usually preferable to stainless steel when necessary to minimize contamination from chromium, nickel and molybdenum. Some contamination from iron is common.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the NDSC EH&S Manual, the Facility Addendum to the NDSC EH&S Manual, and this document.

5.2. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut-resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

Company Confidential & Proprietary

5.3. Exposure to chemicals must be maintained **as low as reasonably achievable**; therefore, unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation where possible. All samples with stickers that read "Caution/Use Hood!" **must** be opened in the hood. Contact the EH&S Coordinator if this is not possible. Solvent and waste containers will be kept closed unless transfers are being made.

5.4. There are no materials used in this method that have a significant or serious hazard rating. A complete list of materials used in the method can be found in the reagents and standards section. Employees must review the information in the Safety Data Sheet (SDS) for each material prior to using it for the first time, or when there are major changes to the SDS.

5.5. All work must be stopped in the event of a known or potential compromise to the health and safety of a Eurofins TestAmerica associate. The situation must be reported **immediately** to the EH&S Coordinator and the Laboratory Supervisor.

5.6. When operating the electric chopper or grinder, be sure to keep all aqueous liquids clear to prevent the risk of electrical shock from any spills.

5.7. Avoid inhalation of sample dust. Work in a ventilation hood when necessary to avoid accidental dust inhalation. Wear a dust mask or respirator if the ventilation hood does not provide sufficient dust protection.

5.8. If there is any malfunction in the equipment. De-energize and tag out.

5.9. All noise levels are below OSHA limits.

5.10. Only trained personnel are permitted to use crushing equipment. A list of trained personnel will be maintained with EH&S and QA.

6. EQUIPMENT AND SUPPLIES

6.1. Butcher Paper

6.2. Plastic wrap

6.3. Aluminum foil

6.4. 8 oz. Glass jars with lids

6.5. Top-loading balance.

6.6. Appropriate containers for each subsample

7. REAGENTS AND STANDARDS

7.1. Deionized water: Reagent water must be produced by a Millipore DI system or equivalent. Reagent water must be free of the analytes of interest as demonstrated through the analysis of preparation blanks.

8. SAMPLE COLLECTION, PRESERVATION, AND STORAGE

8.1. Not applicable to this procedure. Sample collection, preservation, and storage are dependent on the requested test method and analytes.

9. QUALITY CONTROL

9.1. Equipment processing blanks might be applicable for some particle size reduction or selection techniques. There is no single blank matrix that is suitable for all analytes, equipment or processes. The blank matrix should be chosen by the client/data user based on the advantages and limitations described below in Section 9. If no blank matrix is selected by the client, reagent water should be used as the default when possible, as noted in Section 9.2.

9.2. Reagent water (or organic solvents) may be used to rinse the equipment surfaces. This liquid is then analyzed for the target analytes. This process is good at monitoring residue on equipment surfaces from previously processed samples. It does not evaluate the potential contribution of the equipment surface material to a solid sample.

9.3. Sand may be run through processing equipment and then analyzed to monitor for both sample carryover residue and contamination from equipment surface erosion. This process is most applicable for organic analytes. Sand always contains metals. These metals concentrations might be too high for suitable blank demonstrations. Also, the sand material is frequently more abrasive than soil and can over estimate sample contamination due to erosion of the equipment surfaces.

9.4. Teflon boiling chips can be suitable to monitor the cleanliness of processing equipment surfaces. This option is between reagent water and sand regarding abrasion of the equipment surfaces. This material is generally non-detect at parts per billion concentrations for most organic and inorganic analytes. The Teflon material does not mimic the behavior of soil in the subsequent sample extraction or digestion procedures.

9.5. Reprocess half of a field sample and look for differing analyte concentrations between the single and double processed sample aliquots. The occurrence of significantly elevated analyte concentrations in the double processed sample can be a good indication of carryover or contamination due to equipment surface erosion. This is most applicable for monitoring metals contamination in soil grinders.

10. CALIBRATION AND STANDARDIZATION

10.1. Not applicable to this procedure.

11. PROCEDURE

11.1. One-time procedural variations are allowed only if deemed necessary in the professional judgment of QA, operations supervisor, or designee to accommodate variation in sample matrix, chemistry, sample size, or other parameters. Any variation in procedure shall be completely documented using a Nonconformance Memo.

11.2. Any unauthorized deviations from this procedure must also be documented as a nonconformance with a cause and corrective action described.

11.3. Sample Preparation

11.3.1. The following sections describe a variety of procedures. Additional procedures for sample preparation are available in the Soil and Non-Soil Processing SOPs. The client/data user must select the procedure that is most appropriate for the sample matrix, analytes, and quality objectives. The selection of the procedure(s) can be made by the client in consultation with the appropriate laboratory representatives during project planning. There is no single default procedure that can be used in the absence of client selection.

11.3.2. Solid Sample Mixing Procedures

11.3.2.1. In jar mixing

11.3.2.1.1. The flowable sample is thoroughly stirred in the sample jar using a wooden blade.

11.3.2.2. Horizontal surface mixing

11.3.2.2.1. The sample is transferred to an aluminum tray or onto a sheet of paper and mixed with a wooden blade.

11.3.3. Solid Sample Subsampling Procedures

11.3.3.1. Multiple increments from a jar

11.3.3.1.1. Select 5-10 small sample increments from various locations within the sample container to make the entire subaliquot. The increments must come from all general areas of the container--top, sides, center, and bottom.

11.3.3.2. Two dimensional slabcake

11.3.3.2.1. Spread the sample to a consistent depth on a clean flat area covered with an appropriate disposable cover (butcher paper, aluminum tray or foil or plastic depending on the analytes of interest).

11.3.3.2.2. Select 30 or more small increments spread evenly over the sample area or as dictated by client data quality objectives.

The increments must be collected with a blunt end spatula or scoop to evenly collect from the top middle and bottom of the slabcake. A coring device of suitable material can also be used if the sample is sufficiently cohesive (e.g. moist soil).

11.3.3.2.3. If the sample has noxious odors or produces dust, the sample spreading and increment collecting should be performed in a hood or large flat bag of appropriate material. The analyst must be protected from potential inhalation hazards from the sample.

11.3.3.3. Alternate scoop

11.3.3.3.1. Wet or dry solid samples can be divided into two or more smaller aliquots. Determine the number of sub-aliquots, and prepare that many empty containers.

11.3.3.3.2. Scoops of the mixed laboratory sample are either placed in the analytical vessel or discarded.

11.3.3.3.3. Three scoops are discarded for every scoop saved. Randomly select an aliquot and place in the first container. Place the next three aliquots in the second container. Repeat as needed for additional aliquot containers.

11.3.3.3.4. Repeat the aliquoting cycle until the original sample is consumed.

11.3.3.3.5. The alternate scoop technique can also be used to subaliquot discrete samples that are to be homogenized into one composite sample.

11.3.3.3.5.1. Determine approximately the ratio of aliquot to discard scoops required to consume the sample and achieve the aliquot size required for homogenization. For example, if a 50 g aliquot is desired from a 250 g sample, a ratio of one scoop used to four scoops discarded will be used.

11.3.3.3.5.2. For each discrete sample, set up two empty containers of appropriate volume.

11.3.3.3.5.3. Stir each discrete sample in its container, or if necessary homogenize on a sheet of butcher paper and return to the jar.

11.3.3.3.5.4. Place one of the empty containers on a balance and tare it. Place one scoop of sample from the top

of the discrete sample jar into this container. This will be the portion used for a homogenized composite later.

11.3.3.3.5.5. Into the second jar, place the three or more (as determined in Section 11.3.3.3.5.1) scoops to be discarded.

11.3.3.3.5.6. Repeat Sections 11.3.3.3.5.4 and 11.3.3.3.5.5 until the sample has been consumed and the desired weight of the subaliquot is in the tared container. Record the weight of the sub-aliquot.

11.3.3.3.5.7. Repeat this process for all of the discrete samples that will be used for the composite, using approximately equal weights of each discrete sample.

11.3.3.3.5.8. After all discrete samples have been sub-aliquoted using the alternate scoop procedure, combine them on a sheet of butcher paper and homogenize. Pour the homogenized sample volume into the labeled sample jar for the composite sample.

11.3.3.4. One dimensional slabcake

11.3.3.4.1. This process is intended to produce large sub-samples from very large dry flowable solid samples, such as those collected using \incremental sampling methodology, dried and then chopped using the process described in Section 1.1.1See Reference 16.1.7.

11.3.3.4.2. Pour the dry soil sample into a long thin pile onto a clean horizontal surface. The pour height should not exceed 20 cm to minimize the formation of a dust cloud.

11.3.3.4.3. Ensure that the sample container makes at least 20 passes back and forth over the “line of sample.”

11.3.3.4.4. Using a rectangular flat-bottomed scoop, remove an increment from the “line of sample.” Ensure that a complete cross cut of the sample line includes the entire depth of that increment. Combine increments as needed to produce the needed sub-sample size.

11.3.3.5. Cone and quarter (for dry flowable samples)

11.3.3.5.1. Pour the sample into a cone on a clean flat area covered with an appropriate disposable cover (butcher paper, aluminum foil, or plastic depending on the analytes of interest).

11.3.3.5.2. Cut the cone in half in two directions to form four quadrants.

11.3.3.5.3. Return opposite quadrants to the original sample container.

11.3.3.5.4. Repeat the process in Sections 11.3.3.5.1 through 11.3.3.5.3 until the needed aliquot size has been obtained.

11.3.4. Liquid Sample Mixing Procedures

11.3.4.1. Closed container shaking

11.3.4.1.1. All liquid samples should be mixed by shaking in the original closed sample container unless a multiple layer sub-aliquoting procedure is used. This applies to emulsifiable layers such as oil and water and suspendable particulates in water. The sample must remain mixed long enough to pour out a representative aliquot. Samples that show noticeable separation in under a minute should be sub-aliquoted using an appropriate technique as described below.

11.3.4.1.2. The shaking process must be vigorous enough to mix and distribute analytes associated with different layers, particulates, or inside container walls.

11.3.5. Liquid Sample Subsampling Procedures

11.3.5.1. Pour

11.3.5.1.1. Samples that are well mixed can be sub-aliquoted by pouring an appropriate volume off the top of the sample.

11.3.5.2. Layer Subsampling

11.3.5.2.1. Some liquid samples with multiple layers separate too quickly to pour a representative sub-aliquot off the top. In some instances it is best to separate the layers and handle them as individual samples. In other instances representative aliquots of each layer must be collected and processed as a single sub-sample.

11.3.5.2.2. Unless directed otherwise, record the phase ratios (or volumes) of the layers.

11.3.5.2.3. Gravity or Centrifuge Settling

11.3.5.2.3.1. Allow the sample layers to separate based on density. Centrifugation can be used to accelerate the process if simple gravity settling is not fast enough.

11.3.5.2.4. Separatory Funnel

11.3.5.2.4.1. Gently pour the sample into a separatory funnel. Allow time for additional layer separation as needed.

11.3.5.2.4.2. Drain the layers out into separate containers one at a time.

11.3.5.2.4.3. Some oils stick to the separatory funnel sides so the draining process must be slow enough to avoid remixing the layers.

11.3.5.2.5. Pipette

11.3.5.2.5.1. Use a pipette of appropriate size to collect a sub-aliquot of a sample layer of interest and transfer to an empty container.

11.3.5.2.5.2. If the entire sample is to be separated, pipette almost all the top layer into a new container. Draw the small volume of the top layer into the pipette along with a small portion of the second layer. Allow the two layers to separate in the pipette (like a separatory funnel). Dispense the bottom layer back into original sample container with the bulk of the bottom layer. Next dispense the remaining top layer into the container that holds the top layer.

11.3.5.2.5.3. Repeat as needed for each layer of interest.

11.3.5.2.6. Coliwasa

11.3.5.2.6.1. A coliwasa is a “coring device” designed for liquid multi-layer samples. It is a long tube with a short valve at the bottom. When designed and used properly it collects representative aliquots of each layer with each sub-aliquoting immersion.

11.3.5.2.6.2. The volume collected is determined by the diameter of the coliwasa and the height of the sample. The larger the tube diameter or taller the sample height, the larger the volume of sample collected.

11.3.5.2.6.3. Place the foot of the valve and its control rod in the multi-layer sample. Slowly slide the coliwasa tube over the control rod and close the ground glass seal of the valve at the bottom.

11.3.5.2.6.4. Lift the coliwasa by the control rod to keep the valve sealed.

11.3.5.2.6.5. Place the coliwasa over the new sample aliquot container. Grasp the top of the coliwasa tube and slowly lower the control rod a few millimeters to open the foot valve and drain the sample into the container.

11.3.5.2.6.6. Repeat Sections 11.3.5.2.6.3 through 11.3.5.2.6.5 until sufficient sample aliquot has been collected.

11.3.6. Multiphase Sample Mixing Procedures

11.3.6.1. All liquid samples should be mixed by shaking unless a multiple layer subaliquoting procedure is used. This applies to emulsifiable layers such as oil and water and suspendable particulates in water. The sample must remain mixed long enough to pour out a representative aliquot. Samples that show noticeable separation in under a minute should be subaliquoted using an appropriate technique as described below.

11.3.6.2. Closed container shaking

11.3.6.2.1. The shaking process must be vigorous enough to mix and distribute analytes associated with different layers, particulates, or inside container walls.

11.3.6.3. Open container stirring

11.3.6.3.1. The sample is stirred or swirled to mix.

11.3.6.4. Wet Sediments

11.3.6.4.1. Aqueous samples for non-volatile compound analysis may contain settleable materials. If the settleable materials are to be included as part of the laboratory sample, and they will remain suspended, or can easily be re-suspended and will remain so during the subsampling operation, the sample should be handled as a liquid sample. These samples should be gently swirled for 15 seconds or slowly inverted six times to reduce heterogeneity.

11.3.6.4.2. If the liquid portion only is to be used, the settleable material must be allowed to sink to the bottom before withdrawing the subsample.

11.3.6.4.3. If the settleable material will not remain suspended and is to be included in the analysis, the sample should be treated as a multilayered sample.

11.3.7. Multi-phase Sample Subsampling Procedures

11.3.7.1. Multi-layered samples may include liquid/liquid layers, liquid/solid samples, or solid/solid samples.

11.3.7.2. If the liquid portion of a sludge sample can be re-mixed with the solid portion and will re-separate over time, the sample should be handled as a solid sample.

11.3.7.3. If the solid portion will remain suspended or can easily be re-suspended, the sample should be treated as a liquid sample. Mixing may occur by inverting the container or with slight shaking

11.3.7.4. Layer Separating

11.3.7.4.1. Gravity/Centrifuge – The solid/liquid phase separation may be achieved by gently centrifuging the unopened container or by allowing it to sit undisturbed until the solid portion is settled.

11.3.7.4.2. Pipette – For liquid/liquid layers, separate the layers using a pipette. Each layer may be either transferred into another container or directly into the analytical vessel. Each separated portion is then handled as a homogeneous liquid sample.

11.3.7.4.3. Filter/Decant – For liquid/solid layers, the liquid subsample may be obtained by filtering or decanting the liquid portion from the solid portion. The liquid portion is then handled as a homogeneous liquid sample. The solid portion is handled as a solid laboratory sample.

11.4. Sample Analysis

11.4.1. Not applicable to this procedure

11.5. Analytical Documentation

11.5.1. Record all analytical information in LIMS, including any corrective actions or modifications to the method.

11.5.2. Record all standards and reagents in the LIMS reagents module. All standards and reagents are assigned a unique number for identification.

12. DATA ANALYSIS AND CALCULATIONS

12.1. Not applicable to this procedure.

13. METHOD PERFORMANCE

13.1. The Group/Team Leader has the responsibility to ensure this procedure is performed by an associate who has been properly trained in its use and has the required experience.

14. POLLUTION PREVENTION

14.1. It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage, and reagent stability). Employees must abide by the policies in Section 13 of the NDSC EH&S Manual Document No. CW-E-M-001for "Waste management and Pollution Prevention."

15. WASTE MANAGEMENT

15.1. All waste will be disposed of in accordance with Federal, State and Local regulations. Where reasonably feasible, technological changes have been implemented to minimize the potential for pollution of the environment. Employees will abide by this method and the policies in Section 13 of the NDSC EH&S Manual Document No. CW-E-M-001for "Waste Management and Pollution Prevention."

15.2. Waste Streams Produced by the Method

15.2.1. Used wood spatulas, aluminum sheets, butcher paper; discard in solid waste.

15.3. Laboratory personnel assigned to perform hazardous waste disposal procedures must have a working knowledge of the established procedures and practices of Eurofins TestAmerica. They must have training on the hazardous waste disposal practices upon initial assignment to these tasks, followed by annual refresher training.

SECTION 3. INTRODUCTION, SCOPE AND APPLICABILITY

3.1 Introduction and Compliance References

Eurofins TestAmerica Canton's (QA) Manual is a document prepared to define the overall policies, organization objectives and functional responsibilities for achieving the laboratory's QA Program. Governing SOPs are in place within the organization to ensure the proper execution of this QA Manual (refer to Appendix 1). This manual and referenced documents are required reading for all personnel.

The laboratory is a team of people who work together to serve the health and environmental needs of society through science and technology. The laboratory maintains a local perspective in its scope of services and client relations and maintains a national perspective in terms of quality.

As such, this QA Manual has been prepared to assure compliance with The NELAC Institute (TNI) Standard, dated 2009 and 2016; ISO/IEC Guide 17025:2005 and 2017. The policies and procedures listed in Appendix 1 are compliant with the National Divisional Support Center (NDSC) Quality Management Plan (QMP) for Eurofins TestAmerica; Eurofins TestAmerica Canton, and the various accreditation and certification programs which are held by the laboratory to support environmental work (Appendix 2) The QMP provides a summary of Eurofins TestAmerica's quality and data integrity system. It contains requirements and general guidelines under which all Eurofins TestAmerica facilities shall conduct their operations.

Refer to Appendix 3 for a list of additional references for which this QA Manual is compliant; and Appendix 4 for the compliance crosswalk of this manual to the TNI & ISO/IEC Guide 17025 requirements.

3.2 Terms and Definitions

A QA Program is a company-wide system designed to ensure that data produced by the laboratory conforms to the standards set by state and/or federal regulations. The program functions at the local management level through company goals, from guidance at the executive management level, and at the analytical level through Standard Operating Procedures (SOPs) and quality control. Our program is designed to minimize systematic error, encourage constructive, documented problem solving, and provide a framework for continuous improvement within the organization to better serve our clients.

Refer to Appendix 5 for a list of Terms and Acronyms

3.3 .Scope / Fields of Testing

The laboratory analyzes a broad range of environmental and industrial samples. Sample matrices vary among effluent water, groundwater, hazardous waste, sludge and soils. The QA Program contains specific procedures and methods to test samples of differing matrices for chemical, physical and biological parameters. The Program also contains guidelines on maintaining documentation of analytical processes, reviewing results, servicing clients and tracking samples through the laboratory. The technical and service requirements of all analytical requests are

thoroughly evaluated before commitments are made to accept the work. Measurements are made using published reference methods or methods developed and validated by the laboratory.

The methods covered by this manual include the most frequently requested methodologies needed to provide analytical services in the United States and its territories. The specific list of test methods used by the laboratory can be found in LIMS.

Our areas of expertise include:

Standard Services	Specialty Services
• Volatiles • Semivolatiles • Metals • Pesticides/PCBs/Herbicides • Petroleum Hydrocarbons • Waste Characterization • Non-Potable Water Testing • Soil and Surface Water Testing • Sediment and Tissue Testing • Method Development • Shale Oil & Gas Analysis	• Organic Acids • Incremental sampling

NOTE: All current certificates and scopes of accreditation are available on the laboratory's website at www.testamericainc.com.

The approach of this manual is to define the minimum level of quality assurance and quality control necessary to meet these requirements. All methods performed by the laboratory shall meet these criteria as appropriate. In some instances, quality assurance project plans (QAPPs), project specific data quality objectives (DQOs) or local regulations may require criteria other than those contained in this manual. In these cases, the laboratory will abide by the requested criteria following review and acceptance of the requirements by the Laboratory Director and/or the Quality Assurance (QA) Manager. In some cases, QAPPs and DQOs may specify less stringent requirements. The Laboratory Director and the QA Manager must determine if it is in the lab's best interest to follow the less stringent requirements.

Ohio VAP requirements are listed throughout the document.

3.4 Management of the Manual

3.4.1 Review Process

The template on which this manual is based is reviewed annually by Eurofins National Divisional Support Center (NDSC) which houses the Quality Assurance leadership team for Eurofins Environment Testing America. NDSC QA will assure that the template remains in compliance with Section 3.1. This manual itself is reviewed every two years, or as required by state program, such as CA ELAP, by senior laboratory management to assure that it reflects current practices and meets the requirements of the laboratory's clients and regulators as well as the QMP. Occasionally, the manual may need changes in order to meet new or changing regulations and operations. The QA Manager will review the changes in the normal course of business and incorporate changes into revised sections of the document. All updates will be reviewed by the senior laboratory management staff. The laboratory updates and approves

such changes according to our Document Control (NC-QA-030) and Updating Procedures (NC-QA-027).

4 MANAGEMENT REQUIREMENTS

4.1 Overview

The laboratory is a local operating unit of Eurofins Environment Testing America and includes various Service Centers. Service Centers under the direct authority of Eurofins TestAmerica Canton include (but are not limited to) the Cambridge, Cincinnati, Columbus, and Dayton facilities in Ohio and the Grand Rapids and Brighton facilities in Michigan.. The laboratory operational and support staff work under the direction of the Laboratory Director. The laboratory management staff includes directors, managers and group leaders. The organizational chart of the management staff are presented in Figure 4-1. Individual departmental staff lists are maintained in the laboratory's internal intranet. Employee names are provided to demonstrate range and size of departments however the actual staff members may vary over time. The most current Organization Chart may be obtained from Quality Assurance Manager or Laboratory Director.

4.2 Roles and Responsibilities

In order for the QA Program to function properly, all members of the staff must clearly understand and meet their individual responsibilities as they relate to the quality program. The responsibility for quality resides with every employee of the laboratory. All employees have access to the QA Manual, are trained to this manual, and are responsible for upholding the standards therein. Each person carries out his/her daily tasks impartially and in a manner consistent with the goals and in accordance with the procedures in this manual and the laboratory's SOPs. The following descriptions briefly define each role in its relationship to the Quality Assurance Program.

4.2.1 Vice President of Quality and Environmental Health and Safety (VP-QA/EHS)

The Vice President (VP) of QA/EHS reports directly to Eurofins Environment Testing America Chief Operating Officer (COO). With the aid of the NDSC Quality Team Members, Business Unit Managers, and Laboratory Directors, the VP-QA/EHS has the responsibility for the establishment, general overview and Corporate maintenance of the Quality Assurance and EH&S Programs within Eurofins Environment Testing America. Additional responsibilities include:

- Review of QA/QC and EHS aspects of NDSC Official Document national projects and expansions or changes in services.
- Work with various organizations outside of the laboratory to further the development of quality standards and represent the laboratory at various trade meetings.
- Prepare monthly reports for quality and EH&S metrics across the environmental testing laboratories and a summary of any quality and EH&S related initiatives and issues.
- With the assistance of the Executive Management and the EHS Managers, maintenance and implementation of the Eurofins Environment Testing America Environmental, Health and Safety Program.

4.2.2 Quality Directors

There are three (3) Quality Directors within NDSC that report directly to the VP-QA/EHS. These Quality Directors have oversight of the general overview and maintenance of the QA Program within the Eurofins Environment Testing America laboratories. Supported tasks include:

- Monitors laboratory internal audit findings;
- Identifies common laboratory weaknesses; and monitors corrective action closures.
- Develops NDSC quality guidance documents and management tools for ensuring and improving compliance;
- Monitors and communicates DoD/DoE requirements;
- Monitors and communicates regulatory and certification requirements;
- Training and On Boarding
- Laboratory assessments, mentoring, and interventions
- Track/drive root cause investigations and corrective action plans
- Builds knowledge base for preventive actions

4.2.3 Quality Information Manager

The Quality Information works directly with the NDSC Quality Directors and EHS Managers; and reports directly to the VP-QA/EHS. The Quality Information Manager is responsible for the management of:

- NDSC Official Documents
- TALS/LIMS Certification Module Data
- Company's Intranet website
- Company's Regulatory Limits Database
- Subcontract laboratory and approved vendor information
- Internal and External client support for various company groups (e.g., Client Services, EH&S, Legal, IT, Sales) for both quality and operational functions
- Communicate regulatory information and lists

4.2.4 Ethics and Compliance Officers (ECOs)

The NDSC VP-QA/EHS and Corporate Counsel are designated Ethics and Compliance Officer (ECO) –Each ECO acts as a back-up to the other ECO and both are involved when data investigations occur. Each ECO has a direct line of communication to the entire executive management personnel and lab management staff.

The ECOs monitor and audit procedures to determine compliance with policies and to make recommendations for policy enhancements to the President COO, Laboratory Director or other appropriate individuals within the laboratory. The ECO will assist the laboratory QA Manager in the coordination of internal auditing of ethical policy related activities and processes within the laboratory, in conjunction with the laboratory's regular internal auditing function.

The ECOs will also participate in investigations of alleged violations of policies and work with the appropriate internal departments to investigate misconduct, remedy the situation, and prevent recurrence of any such activity.

4.2.5 Environmental Health and Safety (EH&S) Managers

There are 3 EH&S Managers within NDSC that report directly to the VP-QA/EHS. These EH&S Managers have oversight of the general overview and maintenance of the EH&S Program within the Eurofins Environment Testing America laboratories. Supported tasks include:

- Consolidation and tracking all safety and health-related information and reports for the company, and managing compliance activities for Eurofins Environment Testing America locations.
- Coordination/preparation of the Environmental, Health and Safety Manual Template that is used by each laboratory to prepare its own laboratory-specific Safety Manual/ CHP.
- Preparation of information and training materials for laboratory EHS Coordinators.
- Assistance in the coordination of employee exposure and medical monitoring programs to insure compliance with applicable safety and health regulations.
- Serving as Department of Transportation (D.O.T.) focal point and providing technical assistance to location management.
- Serving as Hazardous Waste Management main contact and providing technical assistance to location management.

4.2.6 Laboratory Director

The Laboratory Director is responsible for the overall quality, safety, financial, technical, human resource and service performance of the whole laboratory and reports to their respective business unit President. The Laboratory Director is also responsible for any service centers connected with their laboratory that perform analytical tests, such as short holding time analyses for pH. The Laboratory Director provides the resources necessary to implement and maintain an effective and comprehensive Quality Assurance and Data Integrity Program.

Specific responsibilities include, but are not limited to:

- Provides one or more technical directors for the appropriate fields of testing. If the Technical Director is absent for a period of time exceeding 15 consecutive calendar days, the Laboratory Director must designate another full time staff member meeting the qualifications of the Technical Director to temporarily perform this function. If the absence exceeds 35 consecutive calendar days, the primary accrediting authority must be notified in writing.
- Ensures that all analysts and supervisors have the appropriate education and training to properly carry out the duties assigned to them and ensures that this training has been documented. Works with Eurofins Environment Testing Human Resources for hiring of new personnel.
- Ensures that personnel are free from any commercial, financial and other undue pressures which might adversely affect the quality of their work.
- Ensures company human resource policies are adhered to and maintained.

- Ensures that sufficient numbers of qualified personnel are employed to supervise and perform the work of the laboratory. Assesses laboratory capacity and workload
- Ensures that appropriate corrective actions are taken to address analyses identified as requiring such actions by internal and external performance or procedural audits. Procedures that do not meet the standards set forth in the QA Manual or laboratory SOPs may be temporarily suspended by the Laboratory Director.
- Reviews and approves SOPs as directed by the Quality Assurance department prior to their implementation and ensures all approved SOPs are implemented and adhered to.
- Pursues and maintains appropriate laboratory certification and contract approvals. Supports ISO 17025 requirements.
- Ensures client specific reporting and quality control requirements are met.
- Contributes to the continuous improvement of the laboratory operations.
- Maintains an awareness of technical developments and regulatory requirements.
- Captains the management team, consisting of the QA Manager, the Technical Director, and the Operations Manager as direct reports.

4.2.7 Quality Assurance (QA) Manager or Designee

The QA Manager has responsibility and authority to ensure the continuous implementation of the quality system at the laboratory where they work. The QA Manager is also responsible for any service centers connected with their laboratory that perform analytical tests, such as short holding time analyses for pH.

The QA Manager reports directly to the Laboratory Director and their and their NDSC Quality Director. This position is able to evaluate data objectively and perform assessments without outside (e.g., managerial) influence. The NDSC QA Team may be used as a resource in dealing with regulatory requirements, certifications and other quality assurance related items. The QA Manager directs the activities of the QA office to accomplish specific responsibilities, which include, but are not limited to:

- Serves as the focal point for QA/QC in the laboratory.
- Have functions independent from laboratory operations for which he/she has quality assurance oversight.
- Have documented training and/or experience in QA/QC procedures and the laboratory's Quality System.
- Have a general knowledge of the analytical test methods for which data audit/review is performed (and/or having the means of getting this information when needed).
- Arrange for or conducting internal audits on quality systems and the technical operation
- Notifying laboratory management of deficiencies in the quality system and ensuring corrective action is taken. Procedures that do not meet the standards set forth in the QAM or laboratory SOPs shall be investigated following procedures outlined in Section 12 and if deemed necessary may be temporarily suspended during the investigation.
- Maintaining and updating the QA Manual.

- Monitoring and evaluating laboratory certifications; scheduling proficiency testing samples.
- Monitoring and communicating regulatory changes that may affect the laboratory to management.
- Training and advising the laboratory staff on quality assurance/quality control procedures that are pertinent to their daily activities.
- The laboratory QA Manager or designee will maintain records of all ethics-related training, including the type and proof of attendance.
- Maintain, improve, and evaluate the corrective action database and the corrective and preventive action systems.
- Objectively monitor standards of performance in quality control and quality assurance without outside (e.g., managerial) influence.
- Coordinating of document control of SOPs, MDLs, control limits, and miscellaneous forms and information.
- Performing technical data audits and method audits to ensure consistency and compliance with regulatory requirements.
- Review of external audit reports and data validation requests.
- Follow-up with audits to ensure client QAPP requirements are met.
- Establishment of reporting schedule and preparation of various quality reports for the Laboratory Director, clients and/or NDSC QA Team
- Development of suggestions and recommendations to improve quality systems.
- Research of current state and federal requirements and guidelines.
- Participate in the vendor and supplier approval process, including subcontractors.
- Captains the QA team to enable communication and to distribute duties and responsibilities.
- Communication to the relevant regulatory authorities when there are management or facility changes that impact the laboratory.
- Ensuring Communication & monitoring standards of performance to ensure that systems are in place to produce the level of quality as defined in this document.
- Evaluation of the thoroughness and effectiveness of training.
- Compliance with ISO 17025**.**

4.2.8 Technical Director or Designee

The Technical Director reports directly to the Laboratory Director. He/she is accountable for all analyses and analysts under their experienced supervision and for compliance with the ISO 17025:2017 Standard. The scope of responsibility ranges from the new-hire process and existing technology through the ongoing training and development programs for existing analysts and new instrumentation. Specific responsibilities include, but are not limited to:

- Exercises day-to-day supervision of laboratory operations for the appropriate field of accreditation and reporting of results. Coordinating, writing, and reviewing preparation of all test methods, i.e., SOPs, with regard to quality, integrity, regulatory and optimum and

efficient production techniques, and subsequent analyst training and interpretation of the SOPs for implementation and unusual project samples. He/she insures that the SOPs are properly managed and adhered to at the bench. He/she develops standard costing of SOPs to include supplies, labor, overhead, and capacity (design vs. demonstrated versus first-run yield) utilization.

- Reviewing and approving, with input from the QA Manager, proposals from marketing, in accordance with an established procedure for the review of requests and contracts. This procedure addresses the adequate definition of methods to be used for analysis and any limitations, the laboratory's capability and resources, the client's expectations. Differences are resolved before the contract is signed and work begins. A system documenting any significant changes is maintained, as well as pertinent discussions with the client regarding their requirements or the results of the analyses during the performance of the contract. All work subcontracted by the laboratory must be approved by the client. Any deviations from the contract must be disclosed to the client. Once the work has begun, any amendments to the contract must be discussed with the client and so documented.
- Monitoring the validity of the analyses performed and data generated in the laboratory. This activity begins with reviewing and supporting all new business contracts, insuring data quality, analyzing internal and external non-conformances to identify root cause issues and implementing the resulting corrective and preventive actions, facilitating the data review process (training, development, and accountability at the bench), and providing technical and troubleshooting expertise on routine and unusual or complex problems.
- Providing training and development programs to applicable laboratory staff as new hires and, subsequently, on a scheduled basis. Training includes instruction on calculations, instrumentation management to include troubleshooting and preventive maintenance.
- Enhancing efficiency and improving quality through technical advances and improved LIMS utilization. Capital forecasting and instrument life cycle planning for second generation methods and instruments as well as asset inventory management.
- Coordinating sample management from "cradle to grave," insuring that no time is lost in locating samples.
- Scheduling all QA/QC-related requirements for compliance, e.g., MDLs, etc.
- Captains department personnel to communicate quality, technical, personnel, and instrumental issues for a consistent team approach.
- Coordinates audit responses with the QA Manager.
- Compliance with ISO 17025.

4.2.9 Operations Manager

The Operations Manager manages and directs the analytical production sections of the laboratory. He/She reports directly to the Laboratory Director. He/She assists the Technical Director in determining the most efficient instrument utilization. More specifically, he/she:

- Evaluates the level of internal/external non-conformances for all departments.
- Continuously evaluates production capacity and improves capacity utilization.
- Continuously evaluates turnaround time and addresses any problems that may hinder meeting the required and committed turnaround time from the various departments.

- Develops and improves the training of all analysts in cooperation with the Technical Director and QA Manager and in compliance with regulatory requirements.
- Works with the Departmental Group Leaders to ensure that scheduled instrument maintenance is completed.
- Scheduling all QA/QC-related requirements for compliance, e.g., MDLs, etc.
- Captains department personnel to communicate quality, technical, personnel, and instrumental issues for a consistent team approach.
- Coordinates audit responses with the QA Manager.
- Is responsible for efficient utilization of supplies.
- Constantly monitors and modifies the processing of samples through the departments.
- Fully supports the quality system.

4.2.10 Department Group Leaders

Department Group Leaders report to the Operations Manager. Each one is responsible to:

- Ensure that analysts in their department adhere to applicable SOPs and the QA Manual. They perform frequent SOP and QA Manual review to determine if analysts are in compliance and if new, modified, and optimized measures are feasible and should be added to these documents.
- With regard to analysts, participates in the selection, training (as documented in Section 5.3), development of performance objectives and standards of performance, appraisal (measurement of objectives), scheduling, counseling, discipline, and motivation of analysts and documents these activities in accordance with systems developed by the QA and Personnel Departments. They evaluate staffing sufficiency and overtime needs. Training consists of familiarization with SOP, QC, Safety, and computer systems.
- Encourage the development of analysts to become cross-trained in various methods and/or operate multiple instruments efficiently while performing maintenance and documentation, self-supervise, and function as a department team.
- Provide guidance to analysts in resolving problems encountered daily during sample prep/analysis in conjunction with the Technical Director, Operations Manager, and/or QA Manager. Each is responsible for 100% of the data review and documentation, non-conformance and CPAR issues, the timely and accurate completion of performance evaluation samples and MDLs, for the department.
- Ensure all logbooks are maintained, current, and properly labeled or archived.
- Report all non-conformance conditions to the QA Manager, Technical Director, Operations Manager, and/or Laboratory Director.
- Ensure that preventive maintenance is performed on instrumentation as detailed in the QA Manual or SOPs. Responsible for developing and implementing a system for preventive maintenance, troubleshooting, and repairing or arranging for repair of instruments.
- Maintain adequate and valid inventory of reagents, standards, spare parts, and other relevant resources required to perform daily analysis.
- Achieve optimum turnaround time on analyses and compliance with holding times.

- Conduct efficiency and cost control evaluations on an ongoing basis to determine optimization of labor, supplies, overtime, first-run yield, capacity (designed vs. demonstrated), second- and third-generation production techniques/instruments, and long-term needs for budgetary planning.
- Develop, implement, and enhance calibration programs.
- Provide written responses to external and internal audit issues.

4.2.11 Laboratory Analysts

Laboratory analysts are responsible for conducting analysis and performing all tasks assigned to them by the group leader or supervisor. The responsibilities of the analysts are listed below:

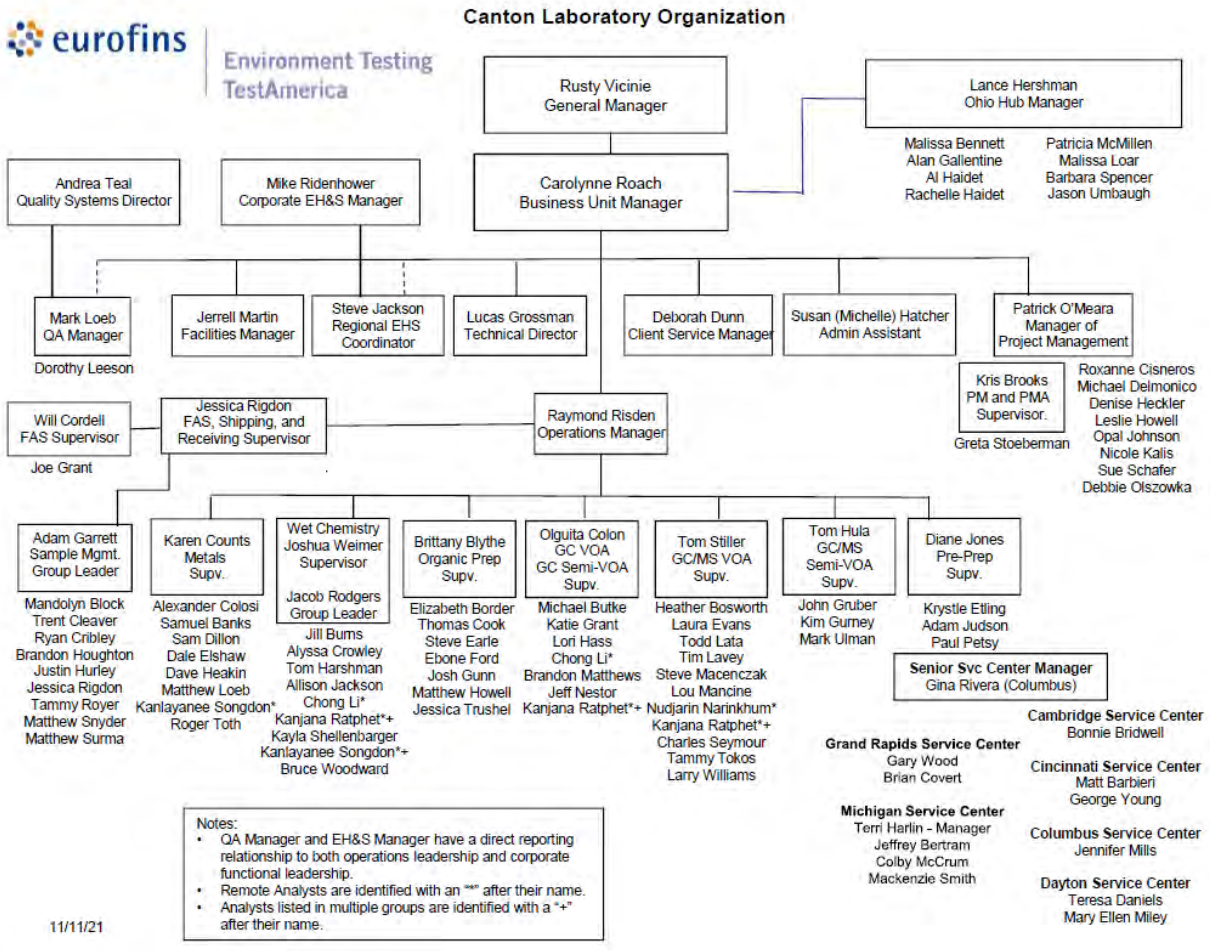
- Perform analyses by adhering to analytical and quality control protocols prescribed by current SOPs, this QA Manual, and project-specific plans honestly, accurately, timely, safely, and in the most cost-effective manner.
- Document standard and sample preparation, instrument calibration and maintenance, data calculations, sample matrix effects, and any observed non-conformance on worklists, benchsheets, lab notebooks and/or the Non-Conformance Database.
- Report all non-conformance situations, instrument problems, matrix problems and QC failures, which might affect the reliability of the data, to their supervisor, the Technical Director, and/or the QA Manager or member of QA staff.
- Perform 100% review of the data generated prior to entering and submitting for secondary level review.
- Suggest method improvements to their supervisor, the Technical Director, and the QA Manager. These improvements, if approved, will be incorporated. Ideas for the optimum performance of their assigned area, for example, through the proper cleaning and maintenance of the assigned instruments and equipment, are encouraged.
- Work cohesively as a team in their department to achieve the goals of accurate results, optimum turnaround time, cost effectiveness, cleanliness, complete documentation, and personal knowledge of environmental analysis.

4.2.12 Project Manager (PM)

Members of the laboratory Client Services/Project Management Group are responsible for organizing and managing client projects. Clients are assigned a project manager who serves as their primary contact at the laboratory. It is the PM's responsibility to act as the client advocate by communicating client requirements to laboratory personnel and ensuring that clients provide complete information needed by the laboratory to meet those requirements – including all verbal communications.
With the overall goal of total client satisfaction, the functions of this position are outlined below:

- Scheduling sample submissions, sample container orders and sample pick-up via the laboratory courier service.
- Confirming certification status
- Coordinating and communicating turnaround time (TAT) requirements for high priority samples/projects.

- Answering common technical questions, facilitating problem resolution and coordinating technical details with the laboratory staff. Ensuring that client specifications, when known, are met by communicating project and quality assurance requirements to the laboratory.
- Notifying the supervisors of incoming projects and sample delivery schedules.
- Accountable to clients for communicating sample status reports or results prior to receipt of the final report. Monitor the status of all data package projects in-house to ensure timely and accurate delivery of reports.
- Inform clients of data package-related problems and resolve service issues.



4.3 Business Continuity and Contingency Plans

Various policies and practices are in place to address continuity of business and contingency plans to ensure continued operations or minimal disruption in operations should unplanned events (natural disasters, unexpected management changes, etc.) occur. Deputies are identified for all key management personnel. Deputies would temporarily fill a role if the primary is absent for more than 15 consecutive calendar days. The deputies must meet the same qualifications as the primary person should they be required to take on the responsibilities. The QA Manager communicates to the relevant regulatory authorities when there are management or facility changes that impact the laboratory. Changes in the technical director must be communicated within a period of time and in the manner dictated by each regulatory authority.

The following table defines who assumes the responsibilities of key personnel in their absence:

Key Personnel	Deputy
Laboratory Director	Technical Director QA Manager
Operations Manager	Technical Director Laboratory Director
Quality Assurance Manager	Quality Assurance Coordinator Laboratory Director
Technical Director	Operations Manager Laboratory Group Leaders
EHS Coordinator	EHS Manager Operations Manager

Figure 4-1. Laboratory Organization Charts
Note: *Organization Charts are subject to change without notice.*

5.0 PERSONNEL

5.1 Overview

The laboratory's management believes that its highly qualified and professional staff is the single most important aspect in assuring a high level of data quality and service. The staff consists of professionals and support personnel.

All personnel must demonstrate competence in the areas where they have responsibility. Any staff that is undergoing training shall have appropriate supervision until they have demonstrated their ability to perform their job function on their own. Staff shall be qualified for their tasks based on appropriate education, training, experience and/or demonstrated skills as required.

The laboratory employs sufficient personnel with the necessary education, training, technical knowledge and experience for their assigned responsibilities.

All personnel are responsible for complying with all QA/QC requirements that pertain to the laboratory and their area of responsibility. Each staff member must have a combination of experience and education to adequately demonstrate a specific knowledge of their particular area of responsibility. Technical staff must also have a general knowledge of lab operations, test methods, QA/QC procedures and records management.

Laboratory management is responsible for formulating goals for lab staff with respect to education, training and skills and ensuring that the laboratory has a policy and procedures for identifying training needs and providing training of personnel. The training shall be relevant to the present and anticipated responsibilities of the lab staff.

The laboratory only uses personnel that are employed by or under contract to, the laboratory. Contracted personnel, when used, must meet competency standards of the laboratory and work in accordance to the laboratory's quality system.

5.2 Education and Experience Requirements for Technical Personnel

The laboratory makes every effort to hire analytical staffs that possess a college degree (AA, BA, BS) in an applied science with some chemistry in the curriculum. Exceptions can be made based upon the individual's experience and ability to learn.

Selection of qualified candidates for laboratory employment begins with documentation of minimum education, training, and experience prerequisites needed to perform the prescribed task. Minimum education and training requirements for laboratory employees are outlined in job descriptions maintained by Eurofins Environment Testing America Human Resources.

Experience and specialized training are occasionally accepted in lieu of a college degree (basic lab skills such as using a balance, colony counting, aseptic or quantitation techniques, etc., are also considered).

As a general rule for analytical staff:

Specialty	Education	Experience
Extractions, Digestions, some electrode methods (pH, DO, Redox, etc.), or Titrimetric and Gravimetric Analyses	H.S. Diploma	On the job training (OJT)
GFAA, CVAA, FLAA, Single component or short list Chromatography (e.g., Fuels, BTEX-GC, IC	A college degree in an applied science or 2 years of college and at least 1 year of college chemistry	Or 2 years prior analytical experience is required
ICP, ICPMS, Long List or complex chromatography (e.g., Pesticides, PCB, Herbicides, HPLC, etc.), GCMS	A college degree in an applied science or 2 years of college chemistry	or 5 years of prior analytical experience
Spectra Interpretation	A college degree in an applied science or 2 years of college chemistry	And 2 years relevant experience Or 5 years of prior analytical experience

Specialty	Education	Experience
Technical Managers – **General**	Bachelor's Degree in an applied science or engineering with 24 semester hours in chemistry An advanced (MS, PhD.) degree may substitute for one year of experience	And 2 years experience in environmental analysis of representative analytes for which they will oversee
Technical Managers – **Wet Chem** only (no advanced instrumentation)	Associates degree in an applied science or engineering or 2 years of college with 16 semester hours in chemistry	And 2 years relevant experience
Technical Managers - **Microbiology**	Bachelor's degree in applied science with at least 16 semester hours in general microbiology and biology An advanced (MS, PhD.) degree may substitute for one year of experience	And 2 years of relevant experience

When an analyst does not meet these requirements, they can perform a task under the direct supervision of a qualified analyst, peer reviewer or Technical Manager, and are considered an analyst in training. The person supervising an analyst in training is accountable for the quality of the analytical data and must review and approve data and associated corrective actions.

5.3 Training

The laboratory is committed to furthering the professional and technical development of employees at all levels.

Orientation to the laboratory's policies and procedures, in-house method training, and employee attendance at outside training courses and conferences all contribute toward employee proficiency. Below are examples of various areas of required employee training:

Required Training	Time Frame	Employee Type
Environmental Health & Safety	Prior to lab work	All
Ethics – New Hires	1 week of hire	All
Ethics – Comprehensive	60 days of hire	All
Data Integrity	60 days of hire	Technical and PMs
Quality Assurance	90 days of hire	All

Required Training	Time Frame	Employee Type
Ethics – Comprehensive Refresher	Annually	All
Initial Demonstration of Capability (DOC)	Prior to unsupervised method performance	Technical

The laboratory maintains records of relevant authorization/competence, education, professional qualifications, training, skills and experience of technical personnel (including contracted personnel) as well as the date that approval/authorization was given. These records are kept on file at the laboratory. Also refer to "Demonstration of Capability" in Section 19.

The training of technical staff is kept up to date by:

- Each employee must have documentation in their training file that they have read, understood and agreed to follow the most recent version of the laboratory QA Manual and SOPs in their area of responsibility. This documentation is updated as SOPs are updated.
- Documentation from any training courses or workshops on specific equipment, analytical techniques or other relevant topics.
- Documentation of proficiency (refer to Section 19).
- An Ethics Agreement signed by each staff member (renewed each year) and evidence of annual ethics training.
- A Confidentiality Agreement signed by each staff member signed at the time of employment.
- Human Resources maintains documentation and attestation forms on employment status and records; benefit programs; timekeeping/payroll; and employee conduct (e.g., ethics violations). This information is maintained in the employee's secured personnel file.

Evidence of successful training could include such items as:

- Adequate documentation of training within operational areas, including one-on-one technical training for individual technologies, and particularly for people cross-trained.
- Analysts knowledge to refer to QA Manual for quality issues.
- Analysts following SOPs, i.e., practice matches SOPs.
- Analysts regularly communicate to supervisors and QA if SOPs need revision, rather than waiting for auditors to find problems.

Further details of the laboratory's training program are described in the Laboratory Training SOP NC-QA-028.

5.4 Data Integrity and Ethics Training Program

The laboratory's Ethics and Data Integrity Program is discussed in Section 7.2. Employees are trained as to the legal and environmental repercussions that result from data misrepresentation. Key topics covered in the presentation include:

- Organizational mission and its relationship to the critical need for honesty and full disclosure in all analytical reporting.
- Ethics Policy
- How and when to report ethical/data integrity issues. Confidential reporting.

- Record keeping.
- Discussion regarding data integrity procedures.
- Specific examples of breaches of ethical behavior (e.g. peak shaving, altering data or computer clocks, improper macros, etc., accepting/offering kickbacks, illegal accounting practices, unfair competition/collusion)
- Internal monitoring. Investigations and data recalls.
- Consequences for infractions including potential for immediate termination, debarment, or criminal prosecution.
- Importance of proper written narration / data qualification by the analyst and project manager with respect to those cases where the data may still be usable but are in one sense or another partially deficient.

Additionally, a data integrity hotline (1-800-736-9407) is maintained by the NDSC

6.0 ACCOMMODATIONS AND ENVIRONMENTAL CONDITIONS

6.1 Overview

The laboratory is a 54,440 ft^2 secure laboratory facility with controlled access and designed to accommodate an efficient workflow and to provide a safe and comfortable work environment for employees. All visitors sign in and are escorted by laboratory personnel. Access is controlled by various measures.

The laboratory is equipped with structural safety features. Each employee is familiar with the location, use, and capabilities of general and specialized safety features associated with their workplace. The laboratory provides and requires the use of protective equipment including safety glasses, protective clothing, gloves, etc., OSHA and other regulatory agency guidelines regarding required amounts of bench and fume hood space, lighting, ventilation (temperature and humidity controlled), access, and safety equipment are met or exceeded.

Traffic flow through sample preparation and analysis areas is minimized to reduce the likelihood of contamination. Adequate floor space and bench top area is provided to allow unencumbered sample preparation and analysis space. Sufficient space is also provided for storage of reagents and media, glassware, and portable equipment. Ample space is also provided for refrigerated sample storage before analysis and archival storage of samples after analysis. Laboratory HVAC and deionized water systems are designed to minimize potential trace contaminants.

The laboratory is separated into specific areas for sample receiving, sample preparation, volatile organic sample analysis, non-volatile organic sample analysis, inorganic sample analysis, microbiological sample analysis, and administrative functions.

6.2 Environment

Laboratory accommodation, test areas, energy sources, and lighting are adequate to facilitate proper performance of tests. The facility is equipped with heating, ventilation, and air conditioning (HVAC) systems appropriate to the needs of environmental testing performed at this laboratory.

The environment in which these activities are undertaken does not invalidate the results or adversely affect the required accuracy of any measurements.

The laboratory provides for the effective monitoring, control and recording of environmental conditions that may affect the results of environmental tests as required by the relevant specifications, methods, and procedures. Such environmental conditions include humidity, voltage, temperature, and vibration levels in the laboratory. Spike/surge arrestors are installed to protect against power surge/sag and lightning strikes. A 30 KW natural gas-fueled backup generator is installed to provide power to the I.T. area in the event of a power failure. Additionally, this generator provides power to two walk-in sample storage coolers and several other smaller sample storage coolers. Smaller portable generators are available to provide "spot power" where needed in the event of a power failure.

When any of the method or regulatory required environmental conditions change to a point where they may adversely affect test results, analytical testing will be discontinued until the environmental conditions are returned to the required levels.

Environmental conditions of the facility housing the computer network and LIMS are regulated to protect against raw data loss.

When the laboratory performs laboratory activities at sites or facilities outside its permanent control, it shall ensure that the requirements related to facilities and environmental conditions of this document are met.

Specific requirements for facility and environmental conditions, as well as periodic monitoring of conditions, are given in the Environmental Health & Safety Manual plus each laboratory's Facility Addendum.

When the laboratory performs laboratory activities at sites or facilities outside its permanent control, it shall ensure that the requirements related to facilities and environmental conditions of this document are met.

6.3 Work Areas

There is effective separation between neighboring areas when the activities therein are incompatible with each other. Examples include:

- Microbiological culture handling and sample incubation areas
- Volatile organic chemical handling areas, including sample preparation and waste disposal, and volatile organic chemical analysis areas

Access to and use of all areas affecting the quality of analytical testing is defined and controlled by secure access to the laboratory building as described below in the Building Security section.

Adequate measures are taken to ensure good housekeeping in the laboratory and to ensure that any contamination does not adversely affect data quality. These measures include regular cleaning to control dirt and dust within the laboratory. Work areas are available to ensure an unencumbered work area. Work areas include:

- Access and entryways to the laboratory
- Sample receipt areas
- Sample storage areas
- Chemical and waste storage areas
- Data handling and storage areas
- Sample processing areas
- Sample analysis areas

Refer to the following documents and procedures for specific requirements for microbiological laboratory facility requirements

- TNI V1M5, 1.7.3.7.a

6.4 Responding to Emergencies

Employees must be aware of procedures to respond to all emergencies that might occur in the workplace. Employees must be familiar with the location and proper operation of all emergency equipment, evacuation routes and designated assembly areas for all areas where they work. Refer to the NDSC EH&S Manual Document No. CW-E-M-001. Sec. 7 and the laboratory's local EH&S addendum for complete details. These documents provide direction for situations where normal operations of the laboratory are not possible (e.g., electrical failures, heating/air conditioning failures, fire/building evacuation, computer failures, hazardous material spills, injury to employees, pandemic flu, disruption of phone service, etc.)

In the event that the building or information technology (IT) systems would be severely challenged, a designated disaster recovery team, which includes Facility Management, Maintenance, Safety, Laboratory/Executive Management, Public Relations, IT, QA and other applicable personnel depending on the scope of the disaster, would assemble at a designated area to assess the situation and formulate a plan.

6.5 Building Security

The laboratory is considered a secure facility. All outside doors (except the main lobby entrance) are locked during normal business hours to prevent unauthorized entry. Building key badges are distributed to employees as necessary.

Visitors to the laboratory sign in and out in a visitor's logbook. A visitor is defined as any person who visits the laboratory who is not an employee of the laboratory. In addition to signing into the laboratory, the Environmental Health and Safety Manual contains requirements for visitors and vendors. There are specific safety forms that must be reviewed and signed. Visitors (with the exception of company employees) are escorted by laboratory personnel at all times, or the location of the visitor is noted in the visitor's logbook.

7.0 QUALITY SYSTEM

7.1 Quality Policy Statement

The Quality Policy statement gives employees clear requirements for the production of analytical data. As an organization, all personnel are committed to high quality professional practice, testing and data, and service to our clients.

We strive to provide the highest quality data achievable by:

- Reading and understanding all of the quality documents applicable to each position and implementing the process in our work.
- Following all recordkeeping requirements; describing clearly and accurately all activities performed; recording "real time" as the task is carried out; understanding that it is never acceptable to "back date" entries and should additional information be required at a later date, the actual date and by whom the notation is made must be documented.
- Ensuring data integrity through the completeness, consistency, impartiality and accuracy of the data generated. Data is attributable, legible, contemporaneously recorded, original or a true copy, and accurate (ALCOA). This applies to manual paper documentation and electronic records.
- Providing accountability and traceability for each sample analyzed through proper sample handling, labeling, preparation, instrument calibration/qualification/validation, analysis, and reporting; establishing an audit trail (the who, what, when, and why) that identifies date, time, analyst, instrument used, instrument conditions, quality control samples (where appropriate and/or required by the method), and associated standard material.
- Emphasizing a total quality management process which provides impartiality, accuracy, and strict compliance with agency regulations and client requirements, giving the highest degree of confidence; understanding that meeting the requirements of the next employee in the work flow process is just as important as meeting the needs of the external client.
- Providing thorough documentation and explanation to qualify reported data that may not meet all requirements and specifications, but is still of use to the client; understanding this occurs only after discussion with the client on the data limitations and acceptability of this approach.
- Responding immediately to indications of questionable data, out-of-specification occurrences, equipment malfunctions, and other types of laboratory problems, with investigation and applicable corrective action; documenting these activities completely, including the reasons for the decisions made.
- Providing a work environment that ensures accessibility to all levels of management and encourages questions and expression of concerns on quality issues to management. Eurofins recognizes that the implementation of a quality assurance program requires management's commitment and support as well as the involvement of the entire staff

  Continually improve systems and manage risk to support quality improvement efforts in laboratory, administrative and managerial activities
- To comply with the ISO/IEC 17025:2005 and 2017 International Standard, the 2009 and 2016 TNI Standard and to continually improve the effectiveness of the management system.

7.2 Ethics and Data Integrity

Eurofins Environment Testing America is committed to ensuring the integrity of its data and meeting the quality needs of its clients. The laboratory operates our Ethics and Data Integrity program under the guidance of Eurofin's Key Guidance Document (KGD).The elements of our program include:

- An Ethics Policy (NDSC Document No. CW-L-P-004) and Employee Ethics Statements.

- Ethics and Compliance Officers (ECOs).
- A Training Program.
- Self-governance through disciplinary action for violations.
- A confidential mechanism for anonymously reporting alleged misconduct and a means for conducting internal investigations of all alleged misconduct. (NDSC Document No. CW-L-S-002).
- Procedures and guidance for recalling data if necessary (NDSC Document CW-Q-S-005).
- Effective external and internal monitoring system that includes procedures for internal audits (Section 15).
- Produce results, which are accurate and include QA/QC information that meets client pre-defined Data Quality Objectives (DQOs).
- Present services in a confidential, honest and forthright manner.
- Provide employees with guidelines and an understanding of the Ethical and Quality Standards of our Industry.
- Provide procedures and guidance to ensure the impartiality and confidentiality of all data and customer information.
- Operate our facilities in a manner that protects the environment and the health and safety of employees and the public.
- Obey all pertinent federal, state and local laws and regulations and encourage other members of our industry to do the same.
- Educate clients as to the extent and kinds of services available.
- Assert competency only for work for which adequate personnel and equipment are available and for which adequate preparation has been made.
- Promote the status of environmental laboratories, their employees, and the value of services rendered by them.

7.3 Quality System Documentation

The laboratory's Quality System is communicated through a variety of documents.

- Quality Assurance Manual – Each laboratory has a lab-specific QA manual.
- NDSC Official Documents – Each laboratory may use the Guidance (instructional use) documents at their discretion. Template documents are process documents that the laboratory's need to implement locally by using the document as is or as an outline to define their internal practices that meet the minimum requirements of the template. Required documents need to be implemented as is and listed in the laboratory's document control list.
- Key Guidance Documents (KGDs) - Documents compiled at the Group Service Centre (GSC) level by Functional Leaders (document owners) aimed at providing specific Eurofins groups of employees with guidelines necessary for the good conduct of their respective work.
- Work Instructions – A subset of procedural steps, tasks or forms associated with an operation of a management system (e.g., checklists, preformatted bench sheets, forms).

- Laboratory SOPs and Policies – General and Technical

7.3.1 Order of Precedence

In the event of a conflict or discrepancy between policies, the order of precedence is as follows:

- Quality Management Plan (CMP)
- NDSC Guidance Documents
- KGDs
- Laboratory Quality Assurance Manual (QA Manual)
- Laboratory SOPs and Policies
- Other (Work Instructions (WI), memos, flow charts, etc.)

NOTE: The laboratory has the responsibility and authority to operate in compliance with regulatory requirements of the jurisdiction in which the work is performed. Where the QMP conflicts with those regulatory requirements, the regulatory requirements of the jurisdiction shall hold primacy. The laboratory's QA Manual shall take precedence over the QMP in those cases.

7.4 QA/QC Objectives for the Measurement of Data

Quality Assurance (QA) is responsible for developing planned activities whose purpose is to provide assurance to all levels of management that a quality program is in place within the laboratory, and that it is functioning in an effective manner that is consistent with the requirements of NELAP and any other regulatory agencies (i.e., states) in which the laboratory maintains accreditation.

Quality Control (QC) is generally understood to be limited to the analyses of samples and to be synonymous with the term *"analytical quality control"*. QC refers to the routine application of statistically based procedures to evaluate and control the accuracy of results from analytical measurements. The QC program includes procedures for estimating and controlling precision and bias and for determining reporting limits.

Request for Proposals (RFPs) and Quality Assurance Project Plans (QAPP) provide a mechanism for the client and the laboratory to discuss the data quality objectives in order to ensure that analytical services closely correspond to client needs. In order to ensure the ability of the laboratory to meet the Data Quality Objectives (DQOs) specified in the QAPP, clients are advised to allow time for the laboratory to review the QAPP before being finalized. The client is responsible for developing the QAPP; however, the laboratory will provide support to the client for developing the sections of the QAPP that concern laboratory activities.

Historically, laboratories have described their QC objectives in terms of precision, accuracy, representativeness, comparability, completeness, selectivity and sensitivity (PARCCSS). Each laboratory SOP defines the required QC indicators.

7.4.1 Precision

The objective is to meet the performance for precision demonstrated for the methods on similar samples and to meet DQOs of the EPA and/or other regulatory programs. Precision is defined as the degree of reproducibility of measurements under a given set of analytical conditions (exclusive of field sampling variability). Precision is documented on the basis of replicate analysis, usually duplicate or matrix spike (MS) duplicate samples.

7.4.2 Accuracy

The objective is to meet the performance for accuracy demonstrated for the methods on similar samples and to meet DQOs of the EPA and/or other regulatory programs. Accuracy is defined as the degree of bias in a measurement system. Accuracy may be documented through the use of laboratory control samples (LCS) and/or MS. A statement of accuracy is expressed as an interval of acceptance recovery about the mean recovery.

7.4.3 Representativeness

The objective is to provide data which is representative of the sampled medium. Representativeness is defined as the degree to which data represent a characteristic of a population or set of samples and is a measurement of both analytical and field sampling precision. The representativeness of the analytical data is a function of the procedures used in procuring and processing the samples. The representativeness can be documented by the relative percent difference between separately procured, but otherwise identical samples or sample aliquots.

The representativeness of the data from the sampling sites depends on both the sampling procedures and the analytical procedures. Refer to laboratory SOPs for subsampling and homogenization techniques appropriate to the analytical method.

7.4.4 Comparability

The objective is to provide analytical data for which the accuracy, precision, representativeness, and reporting limit statistics are similar to these quality indicators generated by other laboratories for similar samples, and data generated by the laboratory over time.

Comparability is documented by inter-laboratory studies carried out by regulatory agencies or carried out for specific projects or contracts, by comparison of periodically generated statements of accuracy, precision, and reporting limits with those of other laboratories.

7.4.5 Completeness

The completeness objective for data is 90% (or as specified by a particular project), expressed as the ratio of the valid data to the total data over the course of the project. Data will be considered valid if they are adequate for their intended use. Data usability will be defined in a QAPP, project scope, or regulatory requirement. Data validation is the process for reviewing data to determine its usability and completeness. If the completeness objective is not met, actions will be taken internally and with the data user to improve performance. This may take the form of an audit to evaluate the methodology and procedures as possible sources for the difficulty or may result in a recommendation to use a different method.

7.4.6 Selectivity

Selectivity is defined as the capability of a test method or instrument to respond to a target substance or constituent in the presence of non-target substances. Target analytes are separated

from non-target constituents and subsequently identified/detected through one or more of the following, depending on the analytical method: extractions (separation), digestions (separation), interelement corrections (separation), use of matrix modifiers (separation), specific retention times (separation and identification), confirmations with different columns or detectors (separation and identification), specific wavelengths (identification), specific mass spectra (identification), and specific electrodes (separation and identification).

7.4.7 Sensitivity

Sensitivity refers to the amount of analyte necessary to produce a detector response that can be reliably detected (above the Method Detection Limit) or quantified (above the Reporting Limit).

7.5 Criteria for Quality Indicators

The laboratory maintains tables, housed in LIMS that summarize the precision and accuracy acceptability limits for performed analyses. This summary includes an effective date, is updated each time new limits are generated, and are managed by the laboratory's QA department. Unless otherwise noted, limits within these tables are laboratory generated. Some acceptability limits are derived from US EPA methods when they are required. Where US EPA method limits are not required, the laboratory has developed limits from evaluation of data from similar matrices. Criteria for development of control limits are contained in NC-QA-018 Statistical Evaluation of Data and Development of Control Charts and in Section 24.

7.6 Statistical Quality Control

Statistically-derived precision and accuracy limits are required by selected methods (such as SW-846) and programs [such as the Ohio Voluntary Action Plan (VAP)]. The laboratory routinely utilizes statistically-derived limits to evaluate method performance and determine when corrective action is appropriate. The analysts use the current limits entered into LIMS. The Quality Assurance department maintains an archive of all limits used within the laboratory. If a method defines the QC limits, the method limits are used.

If a method requires the generation of historical limits, the lab develops such limits from recent data in the QC database of LIMS following the guidelines described in Section 24. All calculations and limits are documented and dated when approved and effective. On occasion, a client requests contract-specified limits for a specific project.

Current QC limits are entered and maintained in the LIMS analyte database. As sample results and the related QC are entered into LIMS, the sample QC values are compared with the limits in LIMS to determine if they are within the acceptable range. The analyst then evaluates if the sample needs to be rerun or re-extracted/rerun or if a comment should be added to the report explaining the reason for the QC outlier.

7.6.1 QC Charts

The laboratory's procedures for the creation of control charts are described in laboratory SOP No. NC-QA-018, "Statistical Evaluation of Data and Development of Control Charts." Control charts are created from data stored in the LIMS. The charts are evaluated by QA and/or technical staff to determine if limits need to be updated or to assess the need for corrective actions to improve method performance.

Control charts are used to develop control limits, trouble-shoot analytical problems, and, in conjunction with the non-conformance system, to monitor for trends. Program-specific data

analysis requirements for control charts are followed as required for data generated under those programs. These additional requirements shall be documented in a QAPP.

7.7 Quality System Metrics

In addition to the QC parameters discussed above, the entire Quality System is evaluated on a monthly basis through the use of specific metrics (refer to Section 16). These metrics are used to drive continuous improvement in the laboratory's Quality System.

8.0 DOCUMENT CONTROL

8.1 Overview

The QA Department is responsible for the control of documents used in the laboratory to ensure that approved, up-to-date documents are in circulation and out-of-date (obsolete) documents are archived or destroyed. The following documents, at a minimum, must be controlled:

- Laboratory Quality Assurance (QA) Manual
- Laboratory Standard Operating Procedures (SOP)
- Laboratory Policies
- Work Instructions and Forms
- NDSC Documents[1]
- KGDs[1]

[1]Includes locally implemented documents that are document controlled within the laboratory's document control system. The NDSC and/or KGD documents are only considered controlled when they are read on the intranet site. Printed copies are considered uncontrolled unless the laboratory physically distributes them as controlled documents. A detailed description of the procedure for issuing, authorizing, controlling, distributing, and archiving NDSC Official Documents is found in Document No. CW-Q-S-001, NDSC Document Control and Archiving. The laboratory's internal document control procedure is defined in SOP NC-QA-030 Document Control and in SOP NC-QA-027 Preparation and Management of SOPs.

The laboratory QA Department also maintains access to various references and document sources integral to the operation of the laboratory. This includes reference methods and regulations. Instrument manuals (hard or electronic copies) are also maintained by the laboratory.

The laboratory maintains control of records for raw analytical data and supporting records such as audit reports and responses, logbooks, standard logs, training files, MDL studies, Proficiency Testing (PT) studies, certifications and related correspondence, and corrective action reports. Raw analytical data consists of bound logbooks, instrument printouts, any other notes, magnetic media, electronic data, and final reports.

8.2 Document Approval and Issue

The pertinent elements of the document control system include a unique document title and number, pagination, the total number of pages of the item or an 'end of document' page, the

effective date, revision number, and the laboratory's name. The QA personnel are responsible for the maintenance of this system.

Controlled documents are authorized by the QA Department. In order to develop a new document, a responsible manager submits an electronic draft to the QA Department for suggestions and approval before use. Upon approval, QA personnel add the identifying version information to the document and retains that document as the official document on file. That document is then provided to all applicable operational units. Controlled documents are identified as such and records of their distribution are kept by the QA Department. Document control may be achieved by either electronic or hardcopy distribution.

The QA Department maintains a list of the official versions of controlled documents.

Quality System Policies and Procedures will be reviewed at a minimum of every two years and revised as appropriate. State or client programs may require a different review schedule. Changes to documents occur when a procedural change warrants.

8.3 Procedures for Document Control Policy

For changes to the QA Manual, refer to SOPs NC-QA-027 and CW-Q-S-001. Uncontrolled copies must not be used within the laboratory. Previous revisions and back-up data are stored by the QA department. Electronic copies are stored on the Public server in the SOP folder for the applicable revision.

For changes to SOPs, refer to SOP No. CW-Q-S-002, Writing a Standard Operating Procedure SOP and SOP NC-QA-027 Preparation and Management of Standard Operating Procedures.. The SOPs identified above also define the process of changes to SOPs.

Forms, worksheets, work instructions and information are organized by the QA department in accordance with the procedures specified in laboratory SOP NC-QA-030.

8.4 Obsolete Documents

All invalid or obsolete documents are removed, or otherwise prevented from unintended use. The laboratory has specific procedures as described above to accomplish this. In general, obsolete documents are collected from employees according to distribution lists and are marked obsolete on the cover or destroyed. At least one copy of the obsolete document is archived according to SOP NC-QA-030.

9.0 SERVICE TO THE CLIENT

9.1 Overview

The laboratory has established procedures for the review of work requests and contracts, oral or written. The procedures include evaluation of the laboratory's capability and resources to meet the contract's requirements within the requested time period. All requirements, including the methods to be used, must be adequately defined, documented and understood. For many environmental sampling and analysis programs, testing design is site or program specific and does not necessarily fit into a standard laboratory service or product. It is the laboratory's intent to provide both standard and customized environmental laboratory services to our clients.

A thorough review of technical and QC requirements contained in contracts is performed to ensure project success. The appropriateness of requested methods, and the lab's capability to perform them must be established. Projects, proposals, and contracts are reviewed for adequately defined requirements and the laboratory's capability to meet those requirements. Alternate test methods that are capable of meeting the clients' requirements may be proposed by the lab. A review of the lab's capability to analyze non-routine analytes is also part of this review process.

All projects, proposals and contracts are reviewed for the client's requirements in terms of compound lists, test methodology requested, sensitivity (detection and reporting levels), accuracy, and precision requirements (% Recovery and RPD). The reviewer ensures that the laboratory's test methods are suitable to achieve these requirements and that the laboratory holds the appropriate certifications and approvals to perform the work. The laboratory and any potential subcontract laboratories must be certified, as required, for all proposed tests.

Electronic or hard copy deliverable requirements are evaluated against the laboratory's capacity for production of the documentation.

If the laboratory cannot provide all services but intends to subcontract such services, whether to another Eurofins facility on the same LIMS or to an outside firm, this will be documented and discussed with the client prior to contract approval. (Refer to Section 10 for Subcontracting Procedures.)

The laboratory informs the client of the results of the review if it indicates any potential conflict, deficiency, lack of accreditation, or inability of the lab to complete the work satisfactorily. Any discrepancy between the client's requirements and the laboratory's capability to meet those requirements is resolved in writing before acceptance of the contract. It is necessary that the contract be acceptable to both the laboratory and the client. Amendments initiated by the client and/or Eurofins TestAmerica Canton are documented in writing.

All contracts, QAPPs, Sampling and Analysis Plans (SAPs), contract amendments, and documented communications become part of the project record.

The same contract review process used for the initial review is repeated when there are amendments to the original contract by the client, and the participating personnel are informed of the changes

9.2 Review Sequence and Key Personnel

Appropriate personnel will review the work request at each stage of evaluation.

For routine projects and other simple tasks, a review by the Project Manager (PM) is considered adequate. The PM confirms that the laboratory has any required certifications, that it can meet the clients' data quality and reporting requirements and that the lab has the capacity to meet the clients turn around needs. It is recommended that, where there is a sales person assigned to the account, an attempt should be made to contact that sales person to inform them of the incoming samples.

For new, complex or large projects, the proposed contract is given to the Client Relationship Manager or Proposal Team, who will decide which lab will receive the work based on the scope

of work and other requirements, including certification, testing methodology, and available capacity to perform the work. This review encompasses all facets of the operation. The scope of work is distributed to the appropriate personnel, as needed based on scope of contract, to evaluate all of the requirements shown above (not necessarily in the order below)

- Contract Administrator
- Laboratory Project Manager
- Laboratory Directors and/or Technical Managers
- Account Executives
- Quality Managers Laboratory Environmental Health and Safety Managers/Directors
- The Laboratory Director reviews the formal laboratory quote and makes final acceptance for their facility.

The Sales Director, Contract Administrator, Account Executive or Proposal Coordinator then submits the final proposal to the client.

In the event that one of the above personnel is not available to review the contract, his or her back-up will fulfill the review requirements.

9.3 Balancing Laboratory Capacity and Workload

Evaluating laboratory capacity to perform specific projects is the responsibility of the Laboratory Directors and Managers, and the Client Services director and manager. Many analysts are cross-trained to perform a variety of tests, and there is redundant equipment available in case of malfunctions. This minimizes the need to evaluate small and medium size projects against capacity available to complete them. Large and complex projects are reviewed against capacity estimates before bids are submitted to ensure that the client's analysis schedule is met. Regularly scheduled meetings are held between laboratory management, PMs, Client Services and QA personnel to review progress with current projects, as well as special requirements of new work scheduled for the laboratory. Laboratory capacity and backlog is tracked on a continuous basis using information from the Laboratory Sample Information System (LIMS) including turnaround time, and work in-house.

9.4 **Documentation**

The Contracts Department maintains copies of all signed contracts. Laboratory Project Manager Assistants and/or PMs maintain electronic copies of signed contracts as needed.

Appropriate records are maintained for every contract or work request. All stages of the contract review process are documented and include records of any significant changes. Records are maintained electronically.

The contract will be distributed to and maintained by the appropriate sales/marketing personnel and the Account Executive. A copy of the contract and formal quote will be filed with the laboratory PM and the Laboratory Director.

Records are maintained of pertinent discussions with a client relating to the client's requirements or the results of the work during the period of execution of the contract. The PM keeps a phone log of conversations with the client.

9.4.1 Project-Specific Quality Planning

Communication of contract specific technical and QC criteria is an essential activity in ensuring the success of site specific testing programs. To achieve this goal, a PM is assigned to each client. It is the PM's responsibility to ensure that project-specific technical and QC requirements are effectively evaluated and communicated to the laboratory personnel before and during the project. QA department involvement may be needed to assist in the evaluation of custom QC requirements.

PM's are the primary client contact and they ensure resources are available to meet project requirements. They coordinate opportunities and work with laboratory management and supervisory staff to ensure available resources are sufficient to perform work for the client's project. Prior to work on a new project, the dissemination of project information and/or project opening meetings may occur to discuss schedules and unique aspects of the project. Items to be discussed may include the project technical profile, turnaround times, holding times, methods, analyte lists, reporting limits, deliverables, sample hazards, or other special requirements. The PM introduces new project information to maximize production and client satisfaction, while maintaining quality. Project notes may be associated with each sample batch as a reminder upon sample receipt and analytical processing.

Any change that may occur within an active project is agreed upon between the client/regulatory agency and the PM/laboratory. These changes (e.g., use of a non-standard method or modification of a method) and approvals must be documented prior to implementation. Documentation pertains to any document (e.g., letter, e-mail, variance, contract addendum), which has been signed by both parties.

Such changes are also communicated to the laboratory during operations meetings, via emails, or directly. The laboratory staff is then introduced to the modified requirements via the PM or the individual laboratory Technical Director. After the modification is implemented into the laboratory process, documentation of the modification is made in the case narrative of the data report(s).

The laboratory strongly encourages client visits to the laboratory and for formal/informal information sharing session with employees in order to effectively communicate ongoing client needs as well as project specific details for customized testing programs.

9.5 Special Services

The laboratory cooperates with clients and their representatives to monitor the laboratory's performance in relation to work performed for the client. It is the laboratory's goal to meet all client requirements in addition to statutory and regulatory requirements. The laboratory has procedures to ensure confidentiality to clients (Section 17 and 25).

The laboratory's standard procedures for reporting data are described in Section 25. Special services are also available and provided upon request. These services include:

- Reasonable access for our clients or their representatives to the relevant areas of the laboratory for the witnessing of tests performed for the client.

- Assisting client-specified third party data validators as specified in the client's contract.
- Supplemental information pertaining to the analysis of their samples. Note: An additional charge may apply for additional data/information that was not requested prior to the time of sample analysis or previously agreed upon.

When the client requests a statement of conformity to a specification or standard based on the analysis performed by the laboratory (e.g., pass/fail, in-tolerance/out-of-tolerance), the decision rule shall be clearly defined. Unless inherent in the requested specification or standard, the decision rule selected shall be communicated to the client. Associated reporting requirements are addressed in Section 25.2.18.

9.6 Client Communication

PMs are the primary communication link to the clients. They shall inform their clients of any delays in project completion as well as any non-conformances in either sample receipt or sample analysis. Project management will maintain ongoing client communication throughout the entire client project.

The Technical Director is available to discuss any technical questions or concerns that the client may have.

9.7 Reporting

The laboratory works with our clients to produce any special communication reports required by the contract.

9.8 Client Feedback and Surveys

The laboratory assesses both positive and negative client feedback. The results are used to improve overall laboratory quality and client service. Eurofins Sales and Marketing teams periodically develop lab and client specific surveys to assess client satisfaction. Client satisfaction surveys are sent routinely.

When a complaint is received, we determine, to the best of our ability, the extent of the issue and what data is in question. The person receiving the complaint documents this information and promptly forwards it to the appropriate management personnel where the work in question was performed. If a data reporting error is discovered, the final report and/or data must be regenerated with the correct value(s).

The laboratory staff is responsible for entering client concerns into iCAT. In some cases, a Corrective Action Report is initiated to address and document the situation. While an individual issue may not warrant a formal investigation, QA monitors these issues for potential trends and will issue a CAR if a trend is evident.

10.0SUBCONTRACTING OF TESTS

10.1 Overview

For the purpose of this quality manual, the phrase subcontract laboratory refers to a laboratory external to the Eurofins TestAmerica Canton laboratories. The phrase "work sharing" refers to internal transfers of samples between the Eurofins TestAmerica Canton laboratories. The term outsourcing refers to the act of subcontracting tests.

When contracting with our clients, the laboratory makes commitments regarding the services to be performed and the data quality for the results to be generated. When the need arises to outsource testing for our clients because project scope, changes in laboratory capabilities, capacity, or unforeseen circumstances, we must be assured that the subcontractors or work sharing laboratories understand the requirements and will meet the same commitments we have made to the client. Refer to the NDSC Documents on Subcontracting Procedures (CW-L-S-004). When outsourcing analytical services, the laboratory will assure, to the extent necessary, that the subcontract or work sharing laboratory maintains a program consistent with the requirements of this document, the requirements specified in TNI/ISO 17025 and/or the client's Quality Assurance Project Plan (QAPP). All QC guidelines specific to the client's analytical program are transmitted to the subcontractor and agreed upon before sending the samples to the subcontract facility. Additionally, work requiring accreditation will be placed with an appropriately accredited laboratory. The laboratory performing the subcontracted work will be identified in the final report, as will non-TNI accredited work where required.

PMs or other responsible Client Service members, for the Export Lab (i.e., the Eurofins TestAmerica laboratory that transfers samples to another laboratory) are responsible for obtaining client approval prior to subcontracting any samples. The laboratory will advise the client of a subcontract arrangement in writing and when possible approval from the client shall be obtained and retained in the project folder. Standard Eurofins TestAmerica Terms & Conditions include the flexibility to subcontract samples within the Eurofins TestAmerica laboratories. Therefore, additional advance notification to clients for intra-laboratory subcontracting is not necessary unless specifically required by a client contract.

Note: In addition to the client, some regulating agencies (e.g., USDA) or contracts require notification prior to placing such work.

10.2 Qualifying and Monitoring Subcontractors

Whenever a PM becomes aware of a client requirement or laboratory need where samples must be outsourced to another laboratory, the other laboratory(s) shall be selected based on the following:

- Subcontractors specified by the client - In these circumstances, the client assumes responsibility for the quality of the data generated from the use of a subcontractor.
- Subcontractors reviewed by Eurofins TestAmerica – Firms which have been reviewed by the company and are known to meet standards for accreditations (e.g., State, TNI and DoD/DOE); technical specifications; legal and financial information.

A listing of vendors is available on the Eurofins TestAmerica intranet site.

All Eurofins TestAmerica laboratories are pre-qualified for work sharing provided they hold the appropriate accreditations and can adhere to the project/program requirements. Client approval is not necessary unless specifically required by the contract. In these cases, the client must provide acknowledgement that the samples can be sent to that facility (an e-mail is sufficient documentation or if acknowledgement is verbal, the date, time, and name of person providing acknowledgement must be documented). The originating laboratory is responsible for communicating all technical, quality, and deliverable requirements as well as other contract needs.

10.2.1 When the potential sub-contract laboratory has not been previously approved, Account Executives or PMs may nominate a laboratory as a subcontractor based on need. The decision to nominate a laboratory must be approved by the Client Relations Manager (CRM) or Laboratory Director. The CRM or Laboratory Director requests that the QA Manager or PM begin the process of approving the subcontract laboratory. Refer to the NDSC Document No. CW-L-S-004, Subcontracting Procedures.

Once the appropriate accreditation and legal information is received by the laboratory, it is evaluated for acceptability and forwarded to the NDSC Quality Information Manager (QIM) for review. After the NDSC QIM reviews the documents for completeness, the information is forwarded to the Finance Department for formal signature and contracting with the laboratory. The approved vendor will be added to the approved subcontractor list on the intranet site, and the finance group is concurrently notified.

The client will assume responsibility for the quality of the data generated from the use of a subcontractor they have requested the lab to use. The qualified subcontractors on the intranet site are known to meet minimal standards. Eurofins TestAmerica does not certify laboratories. The subcontractors on our approved list can only be recommended to the extent that we would use them.

10.3 Oversight and Reporting

The status and performance of qualified subcontractors will be monitored by NDSC and includes an annual review process (see Subcontracting SOP CW-L-S-004). Any problems identified will be brought to the attention of Eurofins TestAmerica's Corporate Finance, Legal and Corporate Quality personnel.

- Complaints shall be investigated. Documentation of the complaint, investigation, and corrective action will be maintained in the subcontractor's file on the intranet site. Complaints are posted using the Vendor Performance Report.
- Information shall be updated on the intranet when new information is received from the subcontracted laboratories.
- Subcontractors in good standing will be retained on the intranet listing. Client Service personnel will notify all Eurofins TestAmerica laboratories, NDSC, and Corporate Contracts if any laboratory requires removal from the intranet site. This notification will be posted on the intranet site and e-mailed to all Client Service Personnel, Laboratory Directors, QA Managers, and Sales Personnel.

Prior to initially sending samples to the subcontracted laboratory, the PM confirms their certification status to determine if it's current and scope-inclusive. The information is documented within the project records.

The laboratory's certifications can be viewed on the company's website.

10.3.1 All subcontracted samples must be accompanied by a Eurofins TestAmerica Chain of Custody (COC). A copy of the original COC sent by the client must be available in LIMS for all samples workshared within Eurofins TestAmerica. Client COCs are only forwarded to external subcontractors when samples are shipped directly from the

project site to the subcontractor lab. Under routine circumstances, client COCs are not provided to external subcontractors.

Through communication with the subcontracted laboratory, the PM monitors the status of the subcontracted analyses, facilitates successful execution of the work, and ensures the timeliness and completeness of the analytical report.

Non-TNI accredited work must be identified in the subcontractor's report as appropriate. If TNI accreditation is not required, the report does not need to include this information.

Reports submitted from subcontractor laboratories are not altered and are included in their original form in the final project report. This clearly identifies the data as being produced by a subcontractor facility. If subcontract laboratory data is incorporated into the laboratory's EDD (i.e., imported), the report must explicitly indicate which lab produced the data for which methods and samples.

Note: The results submitted by a Eurofins TestAmerica work sharing laboratory may be transferred electronically and the results reported by the Eurofins TestAmerica work sharing lab are identified on the final report. The report must explicitly indicate which lab produced the data for which methods and samples. The final report must include a copy of the completed COC for all work sharing reports.

10.4 Contingency Planning

The full qualification of a subcontractor may be waived to meet emergency needs. This decision and justification must be documented in the project files, and the 'Purchase Order Terms And Conditions For Subcontracted Laboratory Services' must be sent with the samples and COC.

In the event this provision is utilized, the laboratory (e.g., PM) will be required to verify and document the applicable accreditations of the subcontractor. All other quality and accreditation requirements will still be applicable, but the subcontractor need not have signed a subcontract agreement with Eurofins TestAmerica at this time.

The use of any emergency subcontractor will require the PM to complete a New Vendor Add Form in order to process payment to the vendor and add them to LIMS. This form requires the user to define the subcontractor's category/s of testing and the reason for testing.

10.5 Use of NELAP and A2LA Logo

It is not laboratory policy to use these logos on any company letterhead, including analytical reports.

11.0 PURCHASING SERVICES AND SUPPLIES

11.1 Overview

Evaluation and selection of suppliers and vendors is performed, in part, on the basis of the quality of their products, their ability to meet the demand for their products on a continuous and short term basis, the overall quality of their services, their past history, and competitive pricing. This is achieved through evaluation of objective evidence of quality furnished by the supplier, which can include certificates of analysis, recommendations, and proof of historical compliance

with similar programs for other clients. To ensure that quality critical consumables and equipment conform to specified requirements, which may affect quality, all purchases from specific vendors are approved by a member of the supervisory or management staff.
Contracts will be signed in accordance with NDSC Document No CW-F-WI-036 Eurofins TestAmerica: Spending and Contract Authority (S&CA) Limits and Authorization Matrix for US Environment.. Request for Proposals (RFP's) will be issued where more information is required from the potential vendors than just price. RFP's allow the laboratory to determine if a vendor is capable of meeting requirements such as supplying all of the laboratory facilities, meeting required quality standards and adhering to necessary ethical and environmental standards. The RFP process also allows potential vendors to outline any additional capabilities they may offer.

11.2 Glassware

Glassware used for volumetric measurements must be Class A or verified for accuracy according to laboratory procedure. Pyrex (or equivalent) glass should be used where possible. For safety purposes, thick-wall glassware should be used where available.

11.3 Reagents, Standards & Supplies

Purchasing guidelines for equipment, consumables, and reagents must meet the requirements of the specific method and testing procedures for which they are being purchased. Solvents and acids are pre-tested in accordance with NDSC Document No. CA-Q-S-001 Solvent & Acid Lot Testing & Approval, Approval information for the solvents and acids tested under Document No. CA-Q-S-001 is stored on the SharePoint, under Solvent Approvals. A master list of all tested materials, as well as the certificates of analysis for the materials, is stored in the same location.

11.3.1 Purchasing

Chemical reagents, solvents, glassware, and general supplies are ordered as needed to maintain sufficient quantities on hand. Materials used in the analytical process must be of a known quality. The wide variety of materials and reagents available makes it advisable to specify recommendations for the name, brand, and grade of materials to be used in any determination. This information is contained in the method SOP. The analyst may check the item out of the on-site consignment system that contains items approved for laboratory use. If the item is not in consignment, the analyst must provide the master item number, item description, package size, catalogue page number, and the quantity needed. If an item being ordered is not the exact item requested, approval must be obtained from the Operations Manager or Group Leader prior to placing the order. The purchasing manager places the order.

11.3.2 Receiving

It is the responsibility of the warehouse manager to receive the shipment. It is the responsibility of the analyst who ordered the materials to document the date materials were received. Once the ordered reagents or materials are received, the analyst compares the information on the label or packaging to the original order to ensure that the purchase meets the quality level specified. This is documented through the addition of the received date and initials to the information present on the daily order log.

The purchasing manager verifies the lot numbers of received solvents and acids against the pre-approval lists. If a received material is listed as unapproved, or is not listed, it is

sequestered and returned to the vendor. Alternatively, the laboratory may test the material for the intended use, and if it is acceptable, document the approval on the approval list. Records of any testing performed locally are maintained on the shared "public" folder on the computer network.

Materials may not be released for use in the laboratory until they have been inspected, verified as suitable for use, and the inspection/verification has been documented.

Safety Data Sheets (SDSs) are available online through the Company's intranet website. Anyone may review these for relevant information on the safe handling and emergency precautions of on-site chemicals.

11.3.3 Specifications

Methods used in the laboratory specify the grade of reagent that must be used in the procedure. If the quality of the reagent is not specified, analytical reagent grade will be used. It is the responsibility of the analyst to check the procedure carefully for the suitability of grade of reagent.

Chemicals must not be used past the manufacturer's expiration date and must not be used past the expiration time noted in a method SOP. If expiration dates are not provided, the laboratory may contact the manufacturer to determine an expiration date.

The laboratory assumes a five year expiration date on inorganic dry chemicals and solvents unless noted otherwise by the manufacturer or by the reference source method. Chemicals/solvents should not be used past the manufacturer's or SOP expiration date unless verified as outlined below

- An expiration date **cannot** be extended if the dry chemical/solvent is discolored or appears otherwise physically degraded. In this case, the dry chemical/solvent must be discarded.
- Expiration dates can be extended if the dry chemical/solvent is found to be satisfactory based on acceptable performance of quality control samples (Continuing Calibration Verification (CCV), Blanks, Laboratory Control Sample (LCS), etc.).
- If the dry chemical/solvent is used for the preparation of standards, the expiration dates can be extended 6 months if the dry chemical/solvent is compared to an unexpired independent source in performing the method and the performance of the dry chemical/solvent is found to be satisfactory. The comparison must show that the dry chemical/solvent meets CCV limits. The comparison studies are maintained on-file and available for review in the reagent module of the LIMS.

  Note: Some programs (such as OVAP) do not allow the use of verified standards and/or reagents.

Wherever possible, standards must be traceable to national or international standards of measurement or to national or international reference materials. Records to that effect are available to the user.

Compressed gases in use are checked for pressure and secure positioning daily. To prevent a tank from going to dryness, or introducing potential impurities, the pressure should be closely watched as it decreases to approximately 15% of the original reading, at which point it should be replaced. For example, a standard sized laboratory gas cylinder containing 3,000 psig of gas should be replaced when it drops to approximately 500 psig. The quality of the gases must meet method or manufacturer specification or be of a grade that does not cause any analytical interference.

Water used in the preparation of samples, standards or reagents must have a specific conductivity of less than 1- µmho/cm (or specific resistivity of greater than 1.0 megohm-cm) at 25ºC. The specific conductivity is checked and recorded daily. If the water's specific conductivity is greater than the specified limit, the Facility Manager and Technical Director must be notified immediately in order to notify all departments, decide on cessation (based on intended use) of activities, and make arrangements for correction.

The laboratory may purchase reagent grade (or other similar quality) water for use in the laboratory. This water must be certified clean by the supplier for all target analytes or otherwise verified by the laboratory prior to use. This verification is documented.

Standard lots are verified before first time use if the laboratory switches manufacturers or has historically had a problem with the type of standard.

Purchased bottleware used for sampling must be certified clean and the certificates must be maintained. If uncertified sampling bottleware is purchased, all lots must be verified clean prior to use. This verification must be maintained.

Records of manufacturer's certification and traceability statements are maintained electronically in the LIMS or in binders in each laboratory section. These records include date of receipt, lot number (when applicable), and expiration date (when applicable). Incorporation of the item into the record indicates that the analyst has compared the new certificate with the previous one for the same purpose and that no difference is noted, unless approved and so documented by the Technical Director or QA Manager.

11.3.4 Storage

Reagent and chemical storage is important from the aspects of both integrity and safety. Light-sensitive reagents may be stored in brown-glass containers. Storage conditions are per the NDSC Environmental Health & Safety Manual Document, No. CW-E-M-001), the local laboratory EH&S manual addendum, and method SOPs or manufacturer instructions.

11.4 Purchase of Equipment / Instruments / Software

When a new piece of equipment is needed, either for additional capacity or for replacing inoperable equipment, the analyst or supervisor makes a supply request to the Technical Director and/or the Laboratory Director. If they agree with the request, the procedures outlined in NDSC Document No. CA-T-P-001, Qualified Products List, are followed. A decision is made as to which piece of equipment can best satisfy the requirements. The appropriate written requests are completed and purchasing places the order.

Upon receipt of a new or used piece of equipment, a unique identification name is assigned and added to the equipment list in the LIMS. IT must also be notified so that they can synchronize the instrument for back-ups. Its capability is assessed to determine if it is adequate or not for the specific application. For instruments, a calibration curve is generated, followed by MDLs, Demonstration of Capabilities (DOCs), and other relevant criteria (refer to Section 20). This can be tracked by use of the New Equipment Tracking Form (WI-NC-091). For software, its operation must be deemed reliable and evidence of instrument verification must be retained by the IT Department or QA Department. Software certificates supplied by the vendors are filed with the LIMS Administrator. The manufacturer's operation manual is retained at the bench.

11.5 Services

Service to analytical instruments (except analytical balances) is performed on an as needed basis. Routine preventative maintenance is discussed in Section 22. The need for service is determined by analysts, Group Leaders, and/or the Technical Director. The service providers that perform the services are approved by the Group Leaders or Operations Manager.

Analytical balances are serviced and calibrated annually in accordance with SOP NC-QA-015. The calibration and maintenance services are performed on-site, and the balances are returned to use immediately following successful calibration. Calibration certificates are filed for reference. If the calibration was unsuccessful, the balance is immediately removed from service and segregated pending either further maintenance or disposal.

Calibration services for support equipment such as thermometers, weight sets, autopipettors, etc., are obtained from vendors with current and valid ISO 17025 accreditation for calibration of the specific piece of equipment. Prior to utilizing the vendor's services, the vendor's accreditation status is verified. Once the equipment has been calibrated, the calibration certificates are reviewed by the QA department, and documentation of the review is filed with the calibration certificates. The equipment is then returned to service within the laboratory

11.6 Suppliers

The laboratory selects vendors through a competitive proposal / bid process, strategic business alliances or negotiated vendor partnerships (contracts). The level of control used in the selection process is dependent on the anticipated spending amount and the potential impact on the laboratory's business. Vendors that provide test and measuring equipment, solvents, standards, certified containers, instrument related service contracts or subcontract laboratory services shall be subject to more rigorous controls than vendors that provide off-the-shelf items of defined quality that meet the end use requirements. The purchasing system includes all suppliers/vendors that have been approved for use.

Evaluation of suppliers is accomplished by ensuring the supplier ships the product or material ordered and that the material is of the appropriate quality. This is documented by signing off on packing slips or other supply receipt documents. The purchasing documents contain the data that adequately describe the services and supplies ordered.

Any issues of vendor performance are to be reported immediately by the laboratory staff to the Purchasing Group by completing a Vendor Performance Report.

The Purchasing Group will work through the appropriate channels to gather the information required to clearly identify the problem and will contact the vendor to report the problem and to make any necessary arrangements for exchange, return authorization, credit, etc.

Suppliers are subject to re-evaluation, as deemed appropriate, through the use of Vendor Performance Reports used to summarize and review to determine corrective action necessary, or service improvements required by vendors

The laboratory has access to a listing of all approved suppliers of critical consumables, supplies and services. This information is provided through the purchasing system.

11.6.1 New Vendor Procedure

Laboratory employees who wish to request the addition of a new vendor must complete a Vendor Add Request Form.

New vendors are evaluated based upon criteria appropriate to the products or services provided as well as their ability to provide those products and services at a competitive cost. Vendors are also evaluated to determine if there are ethical reasons or potential conflicts of interest with laboratory employees that would make it prohibitive to do business with them as well as their financial stability. The QA Department and/or the Technical Services Director are consulted with vendor and product selection that have an impact on quality.

12.0 COMPLAINTS

12.1 Overview

The laboratory considers an effective client complaint handling processes to be of significant business and strategic value. Listening to and documenting client concerns captures client knowledge that enables our operations to continually improve processes and client satisfaction. An effective client complaint handling process also provides assurance to the data user that the laboratory will stand behind its data, service obligations and products.

A client complaint is any expression of dissatisfaction with any aspect of our business services (e.g., communications, responsiveness, data, reports, invoicing and other functions) expressed by any party, whether received verbally or in written form. Client inquiries, complaints or noted discrepancies are documented, communicated to management, and addressed promptly and thoroughly.

The laboratory has procedures for addressing both external and internal complaints with the goal of providing satisfactory resolution to complaints in a timely and professional manner.

The nature of the complaint is identified, documented and investigated, and an appropriate action is determined and taken. In cases where a client complaint indicates that an established policy or procedure was not followed, the QA Department must evaluate whether a special audit must be conducted to assist in resolving the issue. A written confirmation or letter to the client, outlining the issue and response taken is recommended as part of the overall action taken.

The process of complaint resolution and documentation utilizes the procedures outlined in Section 14 (Corrective Actions) and is documented following SOP NC-QA-029 Nonconformance

and Corrective Action System. A copy of this procedure will be made available to any interested party on request.

12.2 External Complaints

An employee that receives a complaint initiates the complaint resolution process by first documenting the complaint according to SOP NC-QA-029.

Complaints fall into two categories: correctable and non-correctable. An example of a correctable complaint would be one where a report re-issue would resolve the complaint. An example of a non-correctable complaint would be one where a client complains that their data was repeatedly late. Non-correctable complaints should be reviewed for preventive action measures to reduce the likelihood of future occurrence and mitigation of client impact.

The general steps in the complaint handling process are:

- Receiving and documenting complaints
- Acknowledging receipt of complaint, whenever possible
- Complaint investigation and service recovery
- Process improvement

The laboratory shall inform the initiator of the complaint of the results of the investigation and the corrective action taken, if any.

12.3 Internal Complaints

Internal complaints include, but are not limited to: errors and non-conformances, training issues, internal audit findings, and deviations from methods. Corrective actions may be initiated by any staff member who observes a nonconformance and shall follow the procedures outlined in Section 14. In addition, Executive Management, Sales and Marketing and IT may initiate a complaint by contacting the laboratory or through the corrective action system described in Section 14.

12.4 Management Review

The number and nature of client complaints is reported by the QA Manager to the Laboratory Director and Quality Director in the QA Monthly report. Monitoring and addressing the overall level and nature of client complaints and the effectiveness of the solutions is part of the Annual Management Systems Review (Section 18).

13 CONTROL OF NON-CONFORMING WORK

13.1 Overview

When data discrepancies are discovered or deviations and departures from laboratory SOPs, policies and/or client requests have occurred, corrective action is taken immediately. First, the laboratory evaluates the significance of the nonconforming work. Then, a corrective action plan is initiated based on the outcome of the evaluation. If it is determined that the nonconforming work is an isolated incident, the plan could be as simple as adding a qualifier to the final results and/or making a notation in the case narrative. If it is determined that the nonconforming work is a systematic or improper practices issue, the corrective action plan could include a more in depth

investigation and a possible suspension of an analytical method. In all cases, the actions taken are documented using the laboratory's corrective action system (refer to Section 14).

Due to the frequently unique nature of environmental samples, sometimes departures from documented policies and procedures are needed. When an analyst encounters such a situation, the problem is presented to the supervisor for resolution. The supervisor may elect to discuss it with the Technical Director or have a representative contact the client to decide on a logical course of action. Once an approach is agreed upon, the analyst documents it using the laboratories corrective action system described in Section 14. This information can then be supplied to the client in the form of a footnote or a case narrative with the report.

Project Management may encounter situations where a client may request that a special procedure be applied to a sample that is not standard lab practice. Based on a technical evaluation, the lab may accept or opt to reject the request based on technical or ethical merit. An example might be the need to report a compound that the lab does not normally report. The lab would not have validated the method for this compound following the procedures in Section 19. The client may request that the compound be reported based only on the calibration. Such a request would need to be approved by the Operations Manager and QA Manager, documented and included in the project folder. Deviations **must** also be noted on the final report with a statement that the compound is not reported in compliance with TNI (or the analytical method) requirements and the reason. Data being reported to a non-TNI state would need to note the change made to how the method is normally run.

13.2 Responsibilities and Authorities

Under certain circumstances, the Laboratory Director, a Technical Director, or a member of the QA team may authorize departures from documented procedures or policies. The departures may be a result of procedural changes due to the nature of the sample; a one-time procedure for a client; QC failures with insufficient sample to reanalyze, etc. In most cases, the client will be informed of the departure prior to the reporting of the data. Any departures must be well documented using the laboratory's corrective action procedures. This information may also be documented in logbooks and/or data review checklists as appropriate. Any impacted data must be referenced in a case narrative and/or flagged with an appropriate data qualifier.

Any misrepresentation or possible misrepresentation of analytical data discovered by any laboratory staff member must be reported to facility Senior Management within 24-hours. The Senior Management staff is comprised of the Laboratory Director, the QA Manager, and the Technical Director. The reporting of issues involving alleged violations of the company's Data Integrity or Manual Integration procedures must be conveyed to an ECO (e.g., the VP-QA/EHS) and the laboratory's Quality Director within 24 hours of discovery.

Whether an inaccurate result was reported due to calculation or quantitation errors, data entry errors, improper practices, or failure to follow SOPs, the data must be evaluated to determine the possible effect.

The Laboratory Director, QA Manager, ECOs, VP of Operations and the Quality Directors have the authority and responsibility to halt work, withhold final reports, or suspend an analysis for due cause as well as authorize the resumption of work.

13.3 Evaluation of Significance and Actions Taken

For each nonconforming issue reported, an evaluation of its significance and the level of management involvement needed is made. This includes reviewing its impact on the final data, whether or not it is an isolated or systematic issue, and how it relates to any special client requirements.

The NDSC Document entitled Data Recalls (CW-Q-S-005) is the procedure to be followed when it is discovered that erroneous or biased data may have been reported to clients or regulatory agencies.

The NDSC Document entitled Internal Investigations (CW-L-S-002) is the procedure to be followed for investigation and correction of situations involved alleged incidents of misconduct or violation of the company's ethics policy.

Laboratory level decisions are documented and approved using the laboratory's standard nonconformance/corrective action reporting in lieu of the data recall determination form contained in NDSC Document No. CW-Q-S-005.

13.4 Prevention of Nonconforming Work

If it is determined that the nonconforming work could recur, further corrective actions must be made following the laboratory's corrective action system. Periodically as defined by the laboratory's preventive action schedule, the QA Department evaluates non-conformances to determine if any nonconforming work has been repeated multiple times. If so, the laboratory's corrective action process may be followed.

13.5 Method Suspension / Restriction (Stop Work Procedures)

In some cases, it may be necessary to suspend/restrict the use of a method or target analyte which constitutes significant risk and/or liability to the laboratory. Suspension/restriction procedures can be initiated by any of the persons noted in Section 13.2, Paragraph 5.

Prior to suspension/restriction, confidentiality will be respected, and the problem with the required corrective and preventive action will be stated in writing and presented to the Laboratory Director.

The Laboratory Director shall arrange for the appropriate personnel to meet with the QA Manager as needed. This meeting shall be held to confirm that there is a problem, that suspension/restriction of the method is required and will be concluded with a discussion of the steps necessary to bring the method/target or test fully back on line. In some cases, that may not be necessary if all appropriate personnel have already agreed there is a problem and there is agreement on the steps needed to bring the method, target or test fully back on line. The QA Manager will also initiate a corrective action report as described in Section 14 if one has not already been started. A copy of any meeting notes and agreed upon steps should be e-mailed by the laboratory to their Business Unit President; VP-QA & EHS This e-mail acts as notification of the incident.

After suspension/restriction, the lab will hold all reports to clients pending review. No faxing, mailing or distributing through electronic means may occur. The report must not be posted for viewing on the internet. It is the responsibility of the Laboratory Director to hold all reporting and to notify all relevant laboratory personnel regarding the suspension/restriction (e.g., Project

Management, Log-in, etc.). Clients will NOT generally be notified at this time. Analysis may proceed in some instances depending on the non-conformance issue.

Within 72 hours, the QA Manager will determine if compliance is now met and reports can be released, OR determine the plan of action to bring work into compliance, and release work. A team, with all principals involved (e.g., Laboratory Director, Technical Director, QA Department, Group Leader) can devise a start-up plan to cover all steps from client notification through compliance and release of reports. Project Management and the Directors of Client Services and Sales and Marketing must be notified if clients must be notified or if the suspension/restriction affects the laboratory's ability to accept work. The QA Manager must approve start-up or elimination of any restrictions after all corrective action is complete.

14 CORRECTIVE ACTION

14.1 Overview

A major component of the laboratory's (QA) Program is the problem investigation and feedback mechanism designed to keep the laboratory staff informed on quality related issues and to provide insight to problem resolution. When nonconforming work or departures from policies and procedures in the quality system or technical operations are identified, the corrective action procedure provides a systematic approach to assess the issues, restore the laboratory's system integrity, and prevent reoccurrence. The laboratory employs two systems to manage non-conformances. Issues suspected of being systematic in nature and for which root cause analysis and a formal Corrective Action Report (CAR) are documented in the Incident Corrective Action Tracking (ICAT) database. Routine batch non-conformances, events that are understood to be isolated in nature, are documented in the LIMS non-conformance memo (NCM) system.

14.2 General

Problems within the quality system or within analytical operations may be discovered in a variety of ways, such as QC sample failures, internal or external audits, proficiency testing (PT) performance, client complaints, staff observation, etc.

The purpose of a corrective action system is to:

- Identify non-conformance events and assign responsibility for investigating.
- Resolve non-conformance events and assign responsibility for any required corrective action.
- Identify systematic problems before they become serious.
- Identify and track client complaints and provide resolution.

14.2.1 **Non-Conformance Memo (NCM)** - is used to document the following types of corrective actions:

- Deviations from an established procedure or SOP
- QC outside of limits
- Isolated reporting / calculation errors
- Client complaints
- Discrepancies in materials / goods received vs. manufacturer packing slips (Forms of documentation other than NCMs in LIMS are also acceptable)

14.2.2 **Corrective Actions Documented In the ICAT Database** –

- Internal and external audit findings
- Failed or unacceptable PT results
- Identified poor process or method performance trends
- Systematic reporting / calculation errors
- Data recall investigations
- Questionable trends that are found in the review of NCMs.
- Client complaints
- Excessive revised reports

The ICAT database is used to document background information, track the results of corrective action investigations and root cause analysis, and to provide reports of corrective action plans.

14.3 Closed Loop Corrective Action Process

Any employee in the company can initiate a corrective action. There are four main components to a closed-loop corrective action process once an issue has been identified: Cause Analysis, Selection and Implementation of Corrective Actions (both short and long term), Monitoring of the Corrective Actions, and Follow-up.

14.3.1 Cause Analysis

- Upon discovery of a non-conformance event, the event must be defined and documented. An entry into the ICAT system must be initiated, someone is assigned to investigate the issue and the event is investigated for cause. Table 12-1 provides some general guidelines on determining responsibility for assessment.
- The cause analysis step is the key to the process as a long term corrective action cannot be determined until the cause is determined.
- If the cause is not readily obvious, the Technical Director, Laboratory Director, or QA Manager (or QA designee) is consulted.

14.3.2 Selection and Implementation of Corrective Actions

- Where corrective action is needed, the laboratory shall identify potential corrective actions. The action(s) most likely to eliminate the problem and prevent recurrence are selected and implemented. Responsibility for implementation is assigned.
- Corrective actions shall be to a degree appropriate to the magnitude of the problem identified through the cause analysis.
- Whatever corrective action is determined to be appropriate, the laboratory shall document and implement the changes. The ICAT record is used for this documentation.

14.3.3 Root Cause Analysis

Root Cause Analysis is a class of problem solving (investigative) methods aimed at identifying the basic or causal factor(s) that underlie variation in performance or the occurrence of a significant failure. The root cause may be buried under seemingly innocuous events, many

steps preceding the perceived failure. At first glance, the immediate response is typically directed at a symptom and not the cause. Typically, root cause analysis would be best with three or more incidents to triangulate a weakness. NDSC Document No CA-Q-S-009, Root Cause Analysis provides guidance on this procedure.

Systematically analyze and document the root causes of the more significant problems that are reported. Identify, track, and implement the corrective actions required to reduce the likelihood of recurrence of significant incidents. Trend the root cause data from these incidents to identify root causes that, when corrected, can lead to dramatic improvements in performance by eliminating entire classes of problems.

Identify the one event associated with problem and ask why this event occurred. Brainstorm the root causes of failures; for example, by asking why events occurred or conditions existed; and then why the cause occurred consecutive times until you get to the root cause. For each of these sub events or causes, ask why it occurred. Repeat the process for the other events associated with the incident.

Root cause analysis does not mean the investigation is over. Look at technique or other systems outside the normal indicators. Often creative thinking will find root causes that ordinarily would be missed and continue to plague the laboratory or operation.

14.3.4 Monitoring of the Corrective Actions

- The Group Leader, Operations Manager, and QA Manager are responsible to ensure that the corrective action taken was effective.
- Ineffective actions are documented and re-evaluated until acceptable resolution is achieved. Group Leaders and the Operations Manager are accountable to the Laboratory Director to ensure final acceptable resolution is achieved and documented appropriately.
- The QA Manager or designee reviews monthly NCM and ICAT records for trends. Highlights are included in the QA monthly report (refer to Section 16). If a significant trend develops that adversely affects quality, an audit of the area is performed and corrective action implemented.
- Any out-of-control situations that are not addressed acceptably at the laboratory level may be reported to the NDSC Quality Director by the QA Manager, indicating the nature of the out-of-control situation and problems encountered in solving the situation.

14.3.5 Follow-up Audits

- Follow-up audits may be initiated by the QA Manager or designee and shall be performed as soon as possible when the identification of a nonconformance casts doubt on the laboratory's compliance with its own policies and procedures, or on its compliance with state or federal requirements.
- These audits often follow the implementation of the corrective actions to verify effectiveness. An additional audit would only be necessary when a critical issue or risk to business is discovered.

(Also refer to Section 17.1.4, Special Audits.)

14.4 Technical Corrective Actions

In addition to providing acceptance criteria and specific protocols for technical corrective actions in the method SOPs, the laboratory has general procedures to be followed to determine when departures from the documented policies and procedures and quality control have occurred (refer to Section 13). The documentation of these procedures is through the use of an NCM or record in the ICAT system.

Table 14-1 includes examples of general technical corrective actions. For specific criteria and corrective actions, refer to the analytical methods or specific method SOPs. The laboratory may also maintain Work Instructions on these items that are available upon request.

Table 14-1 provides some general guidelines for identifying the individual(s) responsible for assessing each QC type and initiating corrective action. The table also provides general guidance on how a data set should be treated if associated QC measurements are unacceptable. Specific procedures are included in Method SOPs, Work Instructions, QAM Sections 19 and 20. All corrective actions are reviewed monthly, at a minimum, by the QA Manager and highlights are included in the QA monthly report.

To the extent possible, samples shall be reported only if all quality control measures are acceptable. If the deficiency does not impair the usability of the results, data will be reported with an appropriate data qualifier and/or the deficiency will be noted in the case narrative. Where sample results may be impaired, the Project Manager is notified by an NCM and appropriate corrective action (e.g., reanalysis) is taken and documented**.**

14.5 Basic Corrections

When mistakes occur in records, each mistake shall be crossed-out, [not obliterated (e.g. no white-out)], and the correct value entered alongside. All such corrections shall be initialed (or signed) and dated by the person making the correction. In the case of records stored electronically, the original uncorrected file must be maintained intact and a second corrected-file is created. This same process applies to adding additional information to a record. All additions made later than the initial must also be initialed (or signed) and dated. When corrections are due to reasons other than obvious transcription errors, the reason for the corrections (or additions) shall also be documented.

Table 14-1. Example – General Corrective Action Procedures

QC Activity *(Individual Responsible for Initiation/Assessment)*	Acceptance Criteria	Recommended Corrective Action
Initial Instrument Blank *(Analyst)*	- Instrument response < RL. -See details in Method SOP	- Prepare another blank. - If same response, determine cause of contamination: reagents, environment, instrument equipment failure, etc.
Initial Calibration Standards *(Analyst, Group Leaders)*	- Correlation coefficient > 0.99 or standard concentration value. - % Recovery within acceptance range. - See details in Method SOP.	- Reanalyze standards. - If still unacceptable, remake standards and recalibrate instrument.

QC Activity *(Individual Responsible for Initiation/Assessment)*	Acceptance Criteria	Recommended Corrective Action
Independent Calibration Verification (Second Source) *(Analyst, Group Leaders*	- % Recovery within control limits.	- Remake and reanalyze standard. - If still unacceptable, then remake calibration standards or use new primary standards and recalibrate instrument.
Continuing Calibration Standards *(Analyst, Data Reviewer)*	% Recovery within control limits.	- Reanalyze standard. - If still unacceptable, then recalibrate and rerun affected samples.
Matrix Spike / Matrix Spike Duplicate (MS/MSD) *(Analyst, Data Reviewers)*	- % Recovery within limits documented in LIMS.	- If the acceptance criteria for duplicates or matrix spikes are not met because of matrix interferences, the acceptance of the analytical batch is determined by the validity of the LCS. - If the LCS is within acceptable limits the batch is acceptable. - The results of the duplicates, matrix spikes and the LCS are reported with the data set. - For matrix spike or duplicate results outside criteria the data for that sample shall be reported with qualifiers.
Laboratory Control Sample (LCS) *(Analyst, Data Reviewers)*	- % Recovery within limits specified in LIMS.	- -Check calculations and instrument performance - Re-analyze the LCS and if still outside of control limits, re-prepare and re-analyze all samples in the batch. It is acceptable to report data when the acceptance criteria for the positive control are exceeded high (i.e., high bias) and there are associated samples that are non-detects, then those non-detects may be reported. **Note:** If there is insufficient sample or the holding time cannot be met, contact the project manager for client instruction.
Surrogates *(Analyst, Data Reviewers)*	- % Recovery within limits specified in LIMS.	-Reprep and analyze the QC batch for MB surrogates below control limits -Report data with narrative if the surrogate is biased high and associated samples are < RL
Method Blank (MB)	< Reporting Limit with the exception of Common	- Reanalyze blank. - If still positive, determine source of

QC Activity *(Individual Responsible for Initiation/Assessment)*	Acceptance Criteria	Recommended Corrective Action
(Analyst, Data Reviewers)	Laboratory Contaminants listed in QA-003 QC Policy.	contamination. If necessary, reprocess (i.e. digest or extract) entire sample batch. Report blank results. - Qualify the result(s) if the concentration of a targeted analyte in the MB is at or above the reporting limit AND is > 1/10 of the amount measured in the sample. -Results are acceptable if the same contaminants were not found in the associated samples.
Proficiency Testing (PT) Samples *(QA Department,, Analysts, Group Leaders)*	- Criteria supplied by PT Supplier.	- Any failures must be investigated for cause. Failures may result in the need to repeat a PT sample to show the problem is corrected.
Internal / External Audits *(QA Department, Operations Manager, , Group Leaders, Laboratory Director)*	- Defined in Quality System documentation such as SOPs, QAM, etc.	- Non-conformances must be investigated system and necessary corrections must be made.
Reporting / Calculation Errors (Depends on issue – possible individuals include: Analysts, Data Reviewers, Project Managers, Group Leaders, QA Manager, NDSC QA,)	SOP CW-Q-S-005, Data Recall	- Corrective action is determined by type of error. Follow the procedures in SOP CW-L-S-002 or your lab's CA SOP.
Client Complaints *(Project Managers, Lab Director, QA Department, Sales and Marketing)*	-	- Corrective action is determined by the type of complaint.
QA Monthly Report (Refer to Section 16 for an example) (QA Manager, Lab Director, *Group Leaders*)		- Corrective action is determined by the type of issue.
Health and Safety Violation (EH&S Coordinator, Lab Director, Operations Manager, Group Leaders)	- Environmental Health and Safety (EHS) Manual.	- Non-conformance is investigated.

Note:
1. Except as noted below for certain compounds, the method blank should be below the detection limit. Concentrations up to five times the reporting limit will be allowed for the ubiquitous laboratory and reagent contaminants. This allowance presumes that the detection limit is significantly below any regulatory limit to which the data are to be compared and that blank subtraction will not occur.

15 PREVENTIVE ACTION / IMPROVEMENT

15.1 Overview

The laboratory's preventive action programs improve or eliminate potential causes of nonconforming product and/or nonconformance to the quality system. This preventive action process is a proactive and continuous process of improvement activities that can be initiated through feedback from clients, employees, business providers, and affiliates. The QA Department has the overall responsibility to ensure that the preventive action process is in place, and that relevant information on actions is submitted for management review.

Dedicating resources to an effective preventive action system emphasizes the laboratory's commitment to its QA Program. It is beneficial to identify and address negative trends before they develop into complaints, problems and corrective actions. Additionally, the laboratory continually strives to improve customer service and client satisfaction through continuous improvements to laboratory systems.

Opportunities for improvement may be discovered through any of the following:

- review of the monthly QA Metrics Report,
- trending NCMs,
- review of control charts and QC results,
- trending proficiency testing (PT) results,
- performance of management system reviews,
- trending client complaints,
- review of processing operations, or
- staff observations.

The monthly Management Systems Metrics Report shows performance indicators in all areas of the laboratory and quality system. These areas include revised reports, corrective actions, audit findings, internal auditing and data authenticity audits, client complaints, PT samples, holding time violations, SOPs, ethics training, etc. The metrics report is reviewed monthly by the laboratory management, NDSC QA Team, Local, and Executive Management These metrics are used in evaluating the management and quality system performance on an ongoing basis and provide a tool for identifying areas for improvement.

Items identified as continuous improvement opportunities to the management system may be issued as goals from the annual management systems review, recommendations from internal audits, white papers, Lessons Learned, Technical Services audit report, Technical Best Practices, or as Executive or management initiatives.

The laboratory's corrective action process is integral to implementation of preventive actions. A critical piece of the corrective action process is the implementation of actions to prevent further occurrence of a non-compliance event. Historical review of corrective action and non-conformances provides a valuable mechanism for identifying preventive action opportunities.

15.1.1 The following elements are part of a preventive action/process improvement system:

- Identification of an opportunity for preventive action or process improvement
- Process for the preventive action or improvement
- Define the measurements of the effectiveness of the process once undertaken
- Execution of the preventive action or improvement
- Evaluation of the plan using the defined measurements
- Verification of the effectiveness of the preventive action or improvement
- Close-Out by documenting any permanent changes to the Quality System as a result of the Preventive Action or Process Improvement. Documentation of Preventive Action/process Improvement is incorporated into the monthly QA reports, corrective action process and management review.

15.1.2 Any preventive actions/process improvement undertaken or attempted shall be taken into account during the annual Management Systems Review (Section 16). A highly detailed report is not required; however, a summary of successes and failures within the preventive action program is sufficient to provide management with a measurement for evaluation.

15.2 Management of Change

The Management of Change process is designed to manage significant events and changes that occur within the laboratory. Through these procedures, the potential risks inherent with a new event or change are identified and evaluated. The risks are minimized or eliminated through pre-planning and the development of preventive measures. The types of changes covered under this system include: Facility Changes, Major Accreditation Changes, Addition or Deletion to Division's Capabilities or Instrumentation, Key Personnel Changes, Laboratory Information Management System (LIMS) changes. The laboratory has a graded approach for managing change based on the Management Systems Review.

16. CONTROL OF RECORDS

The laboratory maintains a records management system appropriate to its needs and that complies with applicable standards or regulations as required. The system produces unequivocal, accurate records that document all laboratory activities. The laboratory retains all original observations, calculations and derived data, calibration records and a copy of the analytical report for a minimum of five years after it has been issued. Exceptions for programs with longer retention requirements are discussed in Section 14.1.2.

16.1 Overview

The laboratory has established procedures for identification, collection, indexing, access, filing, storage, maintenance and disposal of quality and technical records. A record index is listed in Table 14-1. More detailed information on retention of specific records is provided in NDSC Document No. CW-L-P-001, Records Retention Policy and CW-L-WI-001, Records Retention/Storage Schedule. Quality records are maintained by the QA department electronically. Electronic files are backed up as part of the regular laboratory backup. Records are of two types; either electronic or hard copy paper formats depending on whether the record is computer or hand generated (some records may be in both formats). Technical records are maintained by the individual analysts under the direct supervision of their group leader.

Table 16-1. Record Index[1]

	Record Types [1]:	**Retention Time:**
Technical Records	- Raw Data - Logbooks[2] - Standards - Certificates - Analytical Records - MDLs/IDLs/DOCs - Lab Reports	5 Years from analytical report issue*
Official Documents	- Quality Assurance Manual (QAM) - Work Instructions - Policies - SOPs - Policy Memorandums - Manuals - Published Methods	Indefinitely
QA Records	- Certifications - Method and Software Validation / Verification Data	Indefinitely
QA Records	- Internal & External Audits/Responses - Corrective/Preventive Actions - Management Reviews - Data Investigation	5 Years from archival* **Data Investigation:** 5 years or the life of the affected raw data storage whichever is greater (beyond 5 years if ongoing project or pending investigation)
Project Records	- Sample Receipt & COC Documents - Contracts and Amendments - Correspondence - QAPP - SAP - Telephone Logbooks - Lab Reports	5 Years from analytical report issue*
Administrative Records	Financial and Business Operations	Refer to NDSC Doc. No. CW-L-WI-001
	EH&S Manual, Permits	Indefinitely
	Disposal Records	Indefinitely
	Employee Handbook	Indefinitely
	Personnel files, Employee Signature & Initials, Administrative Training Records (e.g., Ethics)	Refer to HR Manual
	Administrative Policies	Indefinitely
	Technical Training Records	7 years
	Legal Records	Indefinitely
	HR Records	Refer to NDSC Doc. No. CW-L-WI-001
	IT Records	Refer to NDSC Doc. No.CW-L-WI-001
	NDSC Governance Records	Refer to NDSC Doc. No.CW-L-WI-001
	Sales & Marketing	5 years
	Real Estate	Indefinitely

[1] Record Types encompass hardcopy and electronic records.
[2] Examples of Logbook types: Maintenance, Instrument Run, Preparation (standard and samples), Standard and Reagent Receipt, Archiving, Balance Calibration, Temperature (hardcopy or electronic records).
** Exceptions listed in Table 16-2.*

16.1.1 All records are stored and retained in such a way that they are secure and readily retrievable at the laboratory facility or an offsite location that provides a suitable environment to prevent damage or deterioration and to prevent loss. All records shall be protected against fire, theft, loss, environmental deterioration, and vermin. In the case of electronic records, electronic or magnetic sources, storage media are protected from deterioration caused by magnetic fields and/or electronic deterioration.

Access to the data is limited to laboratory and company employees and shall be documented with an access log**.** Records archived off-site are stored in a secure location where a record is maintained of any entry into the storage facility. Whether on-site or off-site storage is used, logs are maintained in each storage box to note removal and return of records. Retention of records are maintained on-site at the laboratory for approximately one month after their generation and moved offsite for the remainder of the required storage time. Records are maintained for a minimum of five years unless otherwise specified by a client or regulatory requirement.

For raw data and project records, record retention shall be calculated from the date the project report is issued. For other records, such as NDSC and/or KGD Documents, QA, or Administrative Records, the retention time is calculated from the date the record is formally retired. Records related to the programs listed in Table 16-2 have lengthier retention requirements and are subject to the requirements in Section 16.1.3.

16.2 Programs with Longer Retention Requirements

Some regulatory programs have longer record retention requirements than the standard record retention time. These are detailed in Table 16-2 with their retention requirements. In these cases, the longer retention requirement is enacted. If special instructions exist such that client data cannot be destroyed prior to notification of the client, the container or box containing that data is marked as to who to contact for authorization prior to destroying the data.

Table 16-2. Example: Special Record Retention Requirements

Program	[1]Retention Requirement
Michigan Department of Environmental Quality – all environmental data	10 years 12 years for Lead and Copper results
Ohio VAP	10 years and State contacted prior to disposal
OSHA	30 years

[1]Note: Extended retention requirements must be noted with the archive documents or addressed in facility-specific records retention procedures.

16.2.1 The laboratory has procedures to protect and back-up records stored electronically and to prevent unauthorized access to or amendment of these records. All analytical data is maintained as hard copy or in a secure readable electronic format. For analytical reports

that are maintained as copies in PDF format, refer to Section 19.15.1 for more information.

16.2.2 The record keeping system allows for historical reconstruction of all laboratory activities that produced the analytical data, as well as rapid recovery of historical data (Records stored off site should be accessible within 2 days of a request for such records). The history of the sample from when the laboratory took possession of the samples must be readily understood through the documentation. This shall include inter-laboratory transfers of samples and/or extracts.

- The records include the identity of personnel involved in sampling, sample receipt, preparation, or testing. All analytical work contains the initials (at least) of the personnel involved. The laboratory's copy of the COC is stored with the invoice and the work order sheet generated by LIMS. The chain of custody would indicate the name of the sampler. If any sampling notes are provided with a work order, they are kept with this package.

- All information relating to the laboratory facilities' equipment, analytical test methods, and related laboratory activities, such as sample receipt, sample preparation, or data verification are documented.

- The record keeping system facilitates the retrieval of all working files and archived records for inspection and verification purposes (e.g., set format for naming electronic files, set format for what is included with a given analytical data set. SOP NC-QA-019, Records Information Management outlines this procedure. Instrument data is stored sequentially by instrument. A given day's analyses are maintained in the order of the analysis. Run logs are maintained for each instrument or method; a copy of each day's run log or instrument sequence is stored with the data to aid in re-constructing an analytical sequence. Where an analysis is performed without an instrument, electronic spreadsheets are used to record and file data, or the data is manually entered into LIMS at the time of analysis. Standard and reagent information is recorded in logbooks or entered into LIMS for each method as required.

- Changes to hardcopy records shall follow the procedures outlined in Section 12 and 19. Changes to electronic records in LIMS or instrument data are recorded in audit trails.

- The reason for a signature or initials on a document is clearly indicated in the records such as "sampled by," "prepared by," "reviewed by", or "analyzed by".

- All generated data except those that are generated by automated data collection systems, are recorded directly, promptly and legibly in permanent dark ink or entered directly into LIMS at the time the data is generated.

- Hard copy data may be scanned into PDF format for record storage as long as the scanning process can be verified in order to ensure that no data is lost and the data files and storage media must be tested to verify the laboratory's ability to retrieve the information prior to the destruction of the hard copy that was scanned.

- Also refer to Section 19.15.1 'Computer and Electronic Data Related Requirements'.

16.3 Technical and Analytical Records

16.3.1 The laboratory retains records of original observations, derived data and sufficient information to establish an audit trail, calibration records, staff records and a copy of each analytical report issued, for a minimum of five years unless otherwise specified by a client or regulatory requirement. The records for each analysis shall contain sufficient information to enable the analysis to be repeated under conditions as close as possible to the original. The records shall include the identity of laboratory personnel responsible for the sampling, performance of each analysis and reviewing results.

16.3.2 Observations, data and calculations are recorded real-time and are identifiable to the specific task.

16.3.3 Changes to hardcopy records shall follow the procedures outlined in Section 12 and 19. Changes to electronic records in LIMS or instrument data are recorded in audit trails.

The essential information to be associated with analysis, such as strip charts, tabular printouts, computer data files, analytical notebooks, and run logs, include:

- laboratory sample ID code**;**
- Date of analysis; time of analysis is also required if the holding time is seventy-two (72) hours or less, or when time critical steps are included in the analysis (e.g., drying times, incubations, etc.); instrumental analyses have the date and time of analysis recorded as part of their general operations. Where a time critical step exists in an analysis, location for such a time is included as part of the documentation in a specific logbook or on a benchsheet.
- Instrumentation identification and instrument operating conditions/parameters. Operating conditions/parameters are typically recorded in instrument maintenance logs where available.
- analysis type**;**
- all manual calculations and manual integrations**;**
- analyst's or operator's initials/signature**;**
- sample preparation including cleanup, separation protocols, incubation periods or subculture, ID codes, volumes, weights, instrument printouts, meter readings, calculations, reagents**;**
- test results**;**
- standard and reagent origin, receipt, preparation, and use**;**
- calibration criteria, frequency and acceptance criteria**;**
- data and statistical calculations, review, confirmation, interpretation, assessment and reporting conventions**;**
- quality control protocols and assessment**;**
- electronic data security, software documentation and verification, software and hardware audits, backups, and records of any changes to automated data entries
- Method performance criteria including expected quality control requirements. These are indicated both in LIMS and on specific analytical report formats**.**

16.3.4 All logbooks used during receipt, preparation, storage, analysis, and reporting of samples or monitoring of support equipment shall undergo a periodic, documented supervisory or peer review.

16.4 Laboratory Support Activities

In addition to documenting all the above-mentioned activities, the following are retained QA records and project records (previous discussions in this section relate where and how these data are stored):

- all original raw data, whether hard copy or electronic, for calibrations, samples and quality control measures, including analysts' work sheets and data output records (chromatograms, strip charts, and other instrument response readout records);
- a written description or reference to the specific test method used which includes a description of the specific computational steps used to translate parametric observations into a reportable analytical value;
- copies of final reports;
- archived SOPs;
- correspondence relating to laboratory activities for a specific project;
- all corrective action reports, audits and audit responses;
- proficiency test results and raw data; and
- results of data review, verification, and crosschecking procedures

16.4.1 Sample Handling Records

Records of all procedures to which a sample is subjected while in the possession of the laboratory are maintained. These include but are not limited to records pertaining to:

- sample preservation including appropriateness of sample container and compliance with holding time requirement
- sample identification, receipt, acceptance or rejection and login
- sample storage and tracking including shipping receipts, sample transmittal / COC forms
- procedures for the receipt and retention of samples, including all provisions necessary to protect the integrity of samples

16.5 Administrative Records

The laboratory also maintains the administrative records in either electronic or hard copy form. Refer to Table 16-1.

16.6 Records Management, Storage and Disposal

All records (including those pertaining to test equipment), certificates and reports are safely stored, held secure and in confidence to the client. Certification related records are available upon request.

All information necessary for the historical reconstruction of data is maintained by the

laboratory. Records that are stored only on electronic media must be supported by the hardware and software necessary for their retrieval.

Records that are stored or generated by computers or personal computers have hard copy, write-protected backup copies, or an electronic audit trail controlling access.

The laboratory has a record management system (a.k.a., document control) for control of laboratory notebooks, instrument logbooks, standards logbooks, and records for data reduction, validation, storage and reporting. All data are recorded sequentially within a series of sequential notebooks. Bench sheets, if used, are filed sequentially. Standards are maintained in LIMS – no logbooks are required to be used to record that data. Records are considered archived when noted as such in the records management system (a.k.a., document control.)

16.6.1 Transfer of Ownership

In the event that the laboratory transfers ownership or goes out of business, the laboratory shall ensure that the records are maintained or transferred according to client's instructions. Upon ownership transfer, record retention requirements shall be addressed in the ownership transfer agreement and the responsibility for maintaining archives is clearly established. In addition, in cases of bankruptcy, appropriate regulatory and state legal requirements concerning laboratory records must be followed. In the event of the closure of the laboratory, all records will revert to the control of NDSC. Should the entire company cease to exist, as much notice as possible will be given to clients and the accrediting bodies who have worked with the laboratory during the previous 5 years of such action.

16.6.2 Records Disposal

Records are removed from the archive and destroyed after 5 years unless otherwise specified by a client or regulatory requirement. On a project specific or program basis, clients may need to be notified prior to record destruction. Records are destroyed in a manner that ensures their confidentiality such as shredding, mutilation or incineration. (Refer to Tables 14-1 and 14-2).

Electronic copies of records must be destroyed by erasure or physically damaging off-line storage media so no records can be read.

If a third party records Management Company is hired to dispose of records, a "Certificate of Destruction" is required.

17. AUDITS

17.1 Internal Audits

Internal audits are performed to verify that laboratory operations comply with the requirements of the lab's quality system and with the external quality programs under which the laboratory operates. Audits are planned and organized by the QA staff. Personnel conducting the audits should be independent of the area being evaluated. Auditors will have sufficient authority, access to work areas, and organizational freedom necessary to observe all activities affecting quality and to report the assessments to laboratory management and, when requested, to Executive management.

Audits are conducted and documented as described in the NDSC Document No. on performing Internal Auditing, SOP No. CW-Q-S-003. The types and frequency of routine internal audits are described in Table 17-1. Special or ad hoc assessments may be conducted as needed under the direction of the QA staff.

Table 17-1. Types of Internal Audits and Frequency

Description	Performed by	Frequency
Quality Systems Audits	QA Department, QA approved designee, or NDSC QA	All areas of the laboratory annually
Method Audits QA Technical Audits	Joint responsibility: a) QA Manager or designee b) Technical Director or Designee (Refer to NDSC CW-Q-S-003)	QA Technical Audits Frequency: 50% of methods annually
SOP Method Compliance	Joint responsibility: a) QA Manager or designee b) Technical Director or Designee (Refer to NDSC CW-Q-S-003)	SOP Compliance Review Frequency: Every 2 years
Special	QA Department or Designee	Surveillance or spot checks performed as needed, e.g., to confirm corrective actions from other audits.
Performance Testing	Analysts with QA oversight	Two successful per year for each TNI-field of testing or as dictated by regulatory requirements

17.1.1 Annual Quality Systems Audit

An annual quality systems audit is required to ensure compliance to analytical methods and SOPs, Eurofins Data Integrity and Ethics Policies (see Sec. 7.2), TNI quality systems client and state requirements, and the effectiveness of the internal controls of the analytical process, including but not limited to data review, quality controls, preventive action and corrective action. The completeness of earlier corrective actions is assessed for effectiveness & sustainability. The audit is divided into sections for each operating or support area of the lab, and each section is comprehensive for a given area. The area audits may be performed on a rotating schedule throughout the year to ensure adequate coverage of all areas. This schedule may change as situations in the laboratory warrant.

17.1.2 QA Technical Audits

QA technical audits assess data authenticity and analyst integrity. These audits are based on client projects, associated sample delivery groups, and the methods performed. Reported results are compared to raw data to verify the authenticity of results. The validity of calibrations and QC results are compared to data qualifiers, footnotes, and case narratives. Documentation is assessed by examining run logs and records of manual integrations. Manual calculations are checked. Where possible, electronic audit miner programs (e.g., Chrom AuditMiner) are used to

identify unusual manipulations of the data deserving closer scrutiny. QA technical audits will include all methods within a two-year period.

17.1.3 SOP Method Compliance

Compliance of all SOPs with the source methods and compliance of the operational groups with the SOPs will be assessed by the Technical Director or qualified designee at least every two years.

17.1.4 Special Audits

Special audits are conducted on an as needed basis, generally as a follow up to specific issues such as client complaints, corrective actions, PT results, data audits, system audits, validation comments, regulatory audits or suspected ethical improprieties. Special audits are focused on a specific issue, and report format, distribution, and timeframes are designed to address the nature of the issue.

17.1.5 Performance Testing

The laboratory participates semi-annually in performance audits conducted through the analysis of PT samples provided by a third party. The laboratory generally participates in the following types of PT studies: non-potable water and soil

It is Eurofins policy that PT samples be treated as typical samples in the production process. Furthermore, where PT samples present special or unique problems, in the regular production process they may need to be treated differently, as would any special or unique request submitted by any client. The QA Manager must be consulted and in agreement with any decisions made to treat a PT sample differently due to some special circumstance.

Written investigations for unacceptable PT results are required. In some cases it may be necessary for blind QC samples to be submitted to the laboratory to show a return to control.

17.2 External Audits

External audits are performed when certifying agencies or clients conduct on-site inspections or submit performance testing samples for analysis. It is Eurofins policy to cooperate fully with regulatory authorities and clients. The laboratory makes every effort to provide the auditors with access to personnel, documentation, and assistance. Laboratory supervisors are responsible for providing corrective actions to the QA Manager who coordinates the response. Audit responses are due in the time allotted by the client or agency performing the audit.
The laboratory cooperates with clients and their representatives to monitor the laboratory's performance in relation to work performed for the client. The client may only view data and systems related directly to the client's work. All efforts are made to keep other client information confidential.

17.2.1 Confidential Business Information (CBI) Considerations

During on-site audits, auditors may come into possession of information claimed as business confidential. A business confidentiality claim is defined as "a claim or allegation that business information is entitled to confidential treatment for reasons of business confidentiality or a request for a determination that such information is entitled to such treatment." When information is claimed as business confidential, the laboratory must place on (or attach to) the information at the time it is submitted to the auditor, a cover sheet, stamped or typed legend or other suitable form of notice, employing language such as "trade secret", "proprietary" or

"company confidential". Confidential portions of documents otherwise non-confidential must be clearly identified. CBI may be purged of references to client identity by the responsible laboratory official at the time of removal from the laboratory. However, sample identifiers may not be obscured from the information. Additional information regarding CBI can be found in within the 2009 and 2016 TNI standards.

17.3 Audit Findings

Audit findings are documented using the corrective action process and database (see Section 14). The laboratory's corrective action responses may include action plans that could not be completed within a predefined timeframe. In these instances, a completion date must be set and agreed to by operations management and the QA Manager.

Developing and implementing corrective actions to findings is the responsibility of the Group Leader of the department where the finding originated. Findings that are not corrected by specified due dates are reported monthly to management in the QA monthly report.
If any audit finding casts doubt on the effectiveness of the operations or on the correctness or validity of the laboratory's test results, the laboratory shall take timely corrective action, and shall notify clients in writing if the investigations show that the laboratory results have been affected. Once corrective action is implemented, a follow-up audit is scheduled to ensure that the problem has been corrected.

Clients must be notified promptly in writing of any event such as the identification of defective measuring or test equipment that casts doubt on the validity of results given in any test report or amendment to a test report. The investigation must begin within 24 hours of discovery of the problem and all efforts are made to notify the client within two weeks after the completion of the investigation.

18. MANAGEMENT REVIEWS

18.1 Quality Assurance Report

The QA Department is responsible for preparing a comprehensive monthly metrics report to Management to keep them apprised of current quality issues. This report fosters communication, review, and refinement of the QA system to evaluate the suitability of policies and procedures to meet both regulatory and laboratory quality objectives.

The NDSC QA team compiles information from all of the Environment Testing laboratories monthly metrics reports for the Executive Management team. This report includes notable information and concerns regarding the laboratories QA program and a listing of new regulations that may potentially impact the laboratories.

18.2 Annual Management Review

The Laboratory Management team (Laboratory Director, Technical Director, QA Manager / Department, and Operations Manager) conducts a review annually of its quality systems to ensure its continuing suitability and effectiveness in meeting client and regulatory requirements and to introduce any necessary changes or improvements. It will also provide a platform for defining goals, objectives and action items that feed into the laboratory planning system. NDSC personnel may be included in this meeting at the discretion of the Laboratory Director. The LIMS

review consists of examining any audits, complaints or concerns that have been raised through the year that are related to LIMS The laboratory will summarize any critical findings that cannot be solved by the lab and report them to Corporate IT.

This management systems review (NDSC Document No. CW-Q-S-004 and Work Instruction No. CW-Q-WI-003) uses information generated during the preceding year to assess the "big picture" by ensuring that routine actions taken and reviewed on a monthly basis are not components of larger systematic concerns. The monthly review should keep the quality systems current and effective, therefore, the annual review is a formal senior management process to review specific existing documentation. Significant issues from the following documentation are compiled or summarized by the QA Manager prior to the review meeting:

- Matters arising from the previous annual review
- Prior Monthly QA Reports issues
- Laboratory QA Metrics
- Review of report reissue requests
- Review of client feedback and complaints
- Issues arising from any prior management or staff meetings
- Minutes from prior senior lab management meetings - Issues that may be raised from these meetings include:
    - Adequacy of staff, equipment and facility resources
    - Adequacy of policies and procedures
    - Future plans for resources and testing capability and capacity
- The annual internal double blind PT program sample performance (if performed),
- Compliance to the Ethics Policy and Data Integrity Plan - Including any evidence/incidents of inappropriate actions or vulnerabilities related to data Integrity
- Evaluation of overall risk, including risks to impartiality, confidentiality, reporting statements of conformity, and nonconforming work

A report is generated by the QA Manager and management. The report is distributed to the Laboratory Manager and NDSC Quality Director. The report includes, but is not limited to:

- The date of the review and the names and titles of participants
- A reference to the existing data quality related documents and topics that were reviewed
- Quality system or operational changes or improvements that will be made as a result of the review [e.g., an implementation schedule including assigned responsibilities for the changes (Action Table)

Changes to the quality systems requiring update to the laboratory QA Manual shall be included in the next revision of the QA Manual.

18.3 Potential Integrity Related Managerial Reviews

Potential integrity issues (data or business related) must be handled and reviewed in a confidential manner until such time as a follow-up evaluation, full investigation, or other appropriate actions have been completed and issues clarified. The NDSC Document No. CW-L-S-002 Internal Investigations SOP shall be followed All investigations that result in finding of inappropriate activity are documented and include any disciplinary actions involved, corrective actions taken, and all appropriate notifications of clients.

The Eurofins Environment Testing America Presidents, Business Unit Managers, Laboratory Directors, and NDSC Team, are informed of any current data integrity or data recall investigations via the monthly metrics report.

19. TEST METHODS AND METHOD VALIDATION

19.1 Overview

The laboratory uses methods that are appropriate to meet our clients' requirements and that are within the scope of the laboratory's capabilities. These include sampling, handling, transport, storage and preparation of samples, and, where appropriate, an estimation of the measurement of uncertainty as well as statistical techniques for analysis of environmental data.

Instructions are available in the laboratory for the operation of equipment as well as for the handling and preparation of samples. All instructions, Standard Operating Procedures (SOPs), reference methods and manuals relevant to the working of the laboratory are readily available to all staff. Deviations from published methods are documented (with justification) in the laboratory's approved SOPs. SOPs are submitted to clients for review at their request. Significant deviations from published methods require client approval and regulatory approval where applicable.

19.2 Standard Operating Procedures (SOPS)

The laboratory maintains SOPs that accurately reflect all phases of the laboratory such as assessing data integrity, corrective actions, handling customer complaints as well as all analytical methods and sampling procedures. The method SOPs are derived from the most recently promulgated/approved, published methods and are specifically adapted to the laboratory facility. Modifications or clarifications to published methods are clearly noted in the SOPs. All SOPs are controlled in the laboratory.

- All SOPs contain a revision number, effective date, and appropriate approval signatures. Controlled copies are available to all staff.
- Procedures for writing an SOP are incorporated by reference to NDSC Document No. CW-Q-S-002 'Writing a Standard Operating Procedure', No. or the laboratory's SOP NC-QA-027 Preparation and Management of Standard Operating Procedures.
- SOPs are reviewed at a minimum of every 2 years (annually for the state of Kentucky), and where necessary, revised to ensure continuing suitability and compliance with applicable requirements.

19.3 Laboratory Methods Manual

For each test method, the laboratory shall have available the published referenced method as well as the laboratory developed SOP.

Note: If more stringent standards or requirements are included in a mandated test method or regulation than those specified in this manual, the laboratory shall demonstrate that such requirements are met. If it is not clear which requirements are more stringent, the standard from the method or regulation is to be followed. Any exceptions or deviations from the referenced methods or regulations are noted in the specific analytical SOP.

The laboratory maintains an SOP Index for both technical and non-technical SOPs. Technical SOPs are maintained to describe a specific test method. Non-technical SOPs are maintained to describe functions and processes not related to a specific test method.

19.4 Selection of Methods

Since numerous methods and analytical techniques are available, continued communication between the client and laboratory is imperative to assure the correct methods are utilized. Once client methodology requirements are established, this and other pertinent information is summarized by the PM. These mechanisms ensure that the proper analytical methods are applied when the samples arrive for log-in. For non-routine analytical services (e.g., special matrices, non-routine compound lists), the method of choice is selected based on client needs and available technology. The methods selected should be capable of measuring the specific parameter of interest, in the concentration range of interest, and with the required precision and accuracy.

19.4.1 Sources of Methods

Routine analytical services are performed using standard EPA-approved methodology. In some cases, modification of standard approved methods may be necessary to provide accurate analyses of particularly complex matrices. When the use of specific methods for sample analysis is mandated through project or regulatory requirements, only those methods shall be used.

When clients do not specify the method to be used or methods are not required, the methods used will be clearly validated and documented in an SOP and available to clients and/or the end user of the data. Refer to Appendix 6 for a list of the currently accepted U.S. EPA analytical method references used by the laboratory.

The laboratory reviews updated versions to all the aforementioned references for adaptation based upon capabilities, instrumentation, etc., and implements them as appropriate. As such, the laboratory strives to perform only the latest versions of each approved method as regulations allow or require.

Other reference procedures for non-routine analyses may include methods established by specific states (e.g., Underground Storage Tank methods), ASTM or equipment manufacturers. Sample type, source, and the governing regulatory agency requiring the analysis will determine the method utilized.

The laboratory shall inform the client when a method proposed by the client may be inappropriate or out of date. After the client has been informed, and they wish to proceed contrary to the laboratory's recommendation, it will be documented.

19.4.1.1 Client Supplied Methods

Most of the client-supplied method requirements presented to us involve achieving specific quality control criteria, limits of quantitation (LOQ), and/or method detection limits (MDL) using standard EPA methods. These requirements are communicated to the appropriate technical groups prior to the project start up. Each technical group evaluates the scope of work and the requirements to ensure the criteria can be met using the standard EPA method. The data is monitored to ensure the criteria are met throughout the project. The PM notifies the client if there is a more appropriate method available or if the client's criteria cannot be achieved on a certain sample matrix (i.e., due to matrix or dilutions).

Occasionally, we are asked to transfer a non-standardized method from a client into our lab or to develop a new method, when one is not available. In the case of a method transfer, we set up the client's method and perform some initial evaluation. After the initial evaluation, we may make recommendations on how to improve method performance. If the method appears to be adequate, we determine linearity, specificity, precision, accuracy, MDL, and LOQ by performing calibrations, analyzing method blanks, and carrying out method detection limit and IDOC studies.

In the case of method development, we work with the client and/or data user to determine the level of validation required ensuring that the method meets its intended purpose. In addition to the elements above, we also determine standard and sample stability and robustness depending on the scope of the project. Typically, a standard operating procedure is written and submitted to the client with the results of the validation. These steps are completed prior to analysis of field samples. Data related to the setup of the method are archived.

19.4.1.2 Procedural Deviations

Analysts are required to follow a documented method for all tests performed; and any deviations from analytical methods must be documented, approved, and justified in an appropriate and consistent manner. We classify method deviations as either being a planned deviation or an unplanned deviation. In general, the following information is captured to document both types of situations:

- Description of the situation
- Reason or justification for the deviation
- Impact the deviation had on the testing
- Signature/date of analyst performing the test
- Signature/date of QA and Laboratory management approving the deviation
- Signature/date of client approval, if necessary

Deviations to written procedures are documented in raw data records, ICAT or through the ICAR (Investigation and Corrective Action Report) system. Both types of documentation require management and QA review and approval.

19.4.2 Demonstration of Capability

Before the laboratory may institute a new method and begin reporting results, the laboratory shall confirm that it can properly operate the method. In general, this demonstration does not test the performance of the method in real world samples, but in an applicable and available clean matrix sample. If the method is for the testing of analytes that are not conducive to spiking, demonstration of capability may be performed on quality control samples.

A demonstration of capability (DOC, Lab SOP NC-QA-028, Employee Orientation and Training) is performed whenever there is a change in instrument type (e.g., new instrumentation), matrix, method or personnel (e.g., analyst has not performed the test within the last 12 months).

Note: The laboratory shall have a DOC for all analytes included in the methods that the laboratory performs, and proficiency DOCs for each analyst shall include all analytes that the laboratory routinely performs. Addition of non-routine analytes does not require new DOCs for all analysts if those analysts are already qualified for routine analytes tested using identical chemistry and instrument conditions.

The initial demonstration of capability must be thoroughly documented and approved by the Group Leader and QA Manager prior to independently analyzing client samples. All associated documentation must be retained in accordance with the laboratory's archiving procedures.

The laboratory must have an approved SOP, demonstrate satisfactory performance, and conduct an MDL study (when applicable). There may be other requirements as stated within the published method or regulations (e.g., retention time window study).

Note: In some instances, a situation may arise where a client requests that an unusual analyte be reported using a method where this analyte is not normally reported. If the analyte is being reported for regulatory purposes, the method must meet all procedures outlined within this QA Manual (SOP, MDL, and Demonstration of Capability). If the client states that the information is not for regulatory purposes, the result may be reported as long as the following criteria are met:

- The instrument is calibrated for the analyte to be reported using the criteria for the method and ICV/CCV criteria are met (unless an ICV/CCV is not required by the method or criteria are per project DQOs).
- The laboratory's nominal or default reporting limit (RL) is equal to the quantitation limit (QL), must be at or above the lowest non-zero standard in the calibration curve and must be reliably determined. Project RLs are client specified reporting levels which may be higher than the QL. Results reported below the QL must be qualified as estimated values. Also see Section 19.6.1.3, Relationship of Limit of Detection (LOD) to Quantitation Limit (QL).
- The client request is documented and the lab informs the client of its procedure for working with unusual compounds. The final report must be footnoted: *Reporting Limit based on the low standard of the calibration curve.*

19.4.3 Initial Demonstration of Capability (IDOC) Procedures

At least four aliquots must be prepared (including any applicable clean-up procedures) in the same fashion, and following all of the same procedures, as client samples, and analyzed according to the test method (either concurrently or over a period of days).

Using all of the results, calculate the mean recovery in the appropriate reporting units and the standard deviations for each parameter of interest. Refer to SOP NC-QA-028, Employee Orientation and Training, for details on this procedure.

Note: Results of successive LCS analyses can be used to fulfill the DOC requirement.
Methods on line prior to the effective date of this Section shall be updated to the procedures outlined above as new analysts perform their demonstration of capability. A copy of the new record will replace that which was used for documentation in the past. At a minimum, the precision and accuracy of four mid-level laboratory control samples must have been compared to the laboratory's quality control acceptance limits.

19.5 Laboratory Developed Methods and Non-Standard Methods

Any new method developed by the laboratory must be fully defined in an SOP and validated by qualified personnel with adequate resources to perform the method. Method specifications and the relation to client requirements must be clearly conveyed to the client if the method is a non-standard method (not a published or routinely accepted method). The client must also be in agreement to the use of the non-standard method.

19.6 Validation of Methods

Validation is the confirmation by examination and the provision of objective evidence that the particular requirements for a specific intended use are fulfilled.
All non-standard methods, laboratory designed/developed methods, standard methods used outside of their scope, and major modifications to published methods must be validated to confirm they are fit for their intended use. The validation will be as extensive as necessary to meet the needs of the given application. The results are documented with the validation procedure used and contain a statement as to the fitness for use.

19.6.1 Method Validation and Verification Activities for All New Methods

While method validation can take various courses, the following activities can be required as part of method validation. Method validation records are designated QC records and are archived accordingly.

When changes are made to any validated methods, the influence of such changes shall be documented and, if appropriate, a new validation shall be performed.

19.6.1.1 Determination of Method Selectivity – Method selectivity is the demonstrated ability to discriminate the analyte(s) of interest from other compounds in the specific matrix or matrices from other analytes or interference. In some cases to achieve the required selectivity for an analyte, a confirmation analysis is required as part of the method.

19.6.1.2 Determination of Method Sensitivity – Sensitivity can be both estimated and demonstrated. Whether a study is required to estimate sensitivity depends on the level of method development required when applying a particular measurement system to a specific set of samples. Detection limit studies are conducted as described in Section 19.7 below. Where other protocols for estimations and/or demonstrations of sensitivity are required by regulation or client agreement, these shall be followed.

19.6.1.3 Relationship of Limit of Detection (LOD) to the Limit of Quantitation (LOQ) – An important characteristic of expression of sensitivity is the distinction between the LOD and the LOQ. The LOD is the minimum level at which the presence of an analyte can be reliably concluded. The LOQ is the minimum concentration of analyte that can be quantitatively determined with acceptable precision and bias, equivalent to the laboratory's routine reporting limit (RL). For most instrumental measurement systems, there is a region where semi-quantitative data is generated around the LOD (both above and below the estimated MDL or LOD) and below the LOQ. In this region, detection of an analyte may be confirmed but quantification of the analyte is unreliable within the accuracy and precision guidelines of the measurement system. When an analyte is detected below the LOQ, and the presence of the analyte is confirmed by meeting the qualitative identification criteria for the analyte, the analyte can be reliably reported, but the amount of the analyte can only be estimated. If data is to be reported in this region, it must be done so with a qualification that denotes the semi-quantitative nature of the result.

19.6.1.4 Determination of Interferences – A determination that the method is free from interferences in a blank matrix is performed.

19.6.1.5 Determination of Range – Where appropriate to the method, the quantitation range is determined by comparison of the response of an analyte in a curve to established or targeted criteria. Generally the upper quantitation limit is defined by highest acceptable calibration concentration. The lower quantitation limit or QL cannot be lower than the lowest non-zero calibration level, and can be constrained by required levels of bias and precision.

19.6.1.6 Determination of Accuracy and Precision – Accuracy and precision studies are generally performed using replicate analyses, with a resulting percent recovery and measure of reproducibility (standard deviation, relative standard deviation) calculated and measured against a set of target criteria.

19.6.1.7 Documentation of Method – The method is formally documented in an SOP. If the method is a minor modification of a standard laboratory method that is already documented in an SOP, an SOP Attachment describing the specific differences in the new method is acceptable in place of a separate SOP.

19.6.1.8 Continued Demonstration of Method Performance – Continued demonstration of method performance is addressed in the SOP. Continued demonstration of method performance is generally accomplished by batch specific QC samples such as LCS, method blanks or PT samples.

19.7 Method Detection Limits (MDL) / Limits of Detection (LOD)

The MDL is the minimum measured quantity of a substance that can be reported with 99% confidence that the concentration is distinguishable from method blank results, consistent with

40CFR Part 136 Appendix B, August, 2017. The MDL is equivalent to the TNI LOD, and is also equivalent to the DoD/DOE Quality Systems Manual (QSM) DL. The working or final MDL is the higher of the MDL value determined from spikes (MDLs) and the MDL value determined from blanks (MDLb). An initial MDL study shall be performed during the method validation process and when the method is altered in a way that can reasonably be expected to change its sensitivity. On-going data are collected during each quarter in which samples are being analyzed. At least once every 13 months the MDLs and MDLb are re-calculated and re-evaluated using data collected during the preceding period. Details of the laboratory's procedure for conducting MDL studies are given in NDSC Document No. CA-Q-S-006.

19.8 Verification of Detection Limits

If it is found during the re-evaluation of detection limit results that more than 5% of the spiked samples do not return positive numeric results that meet all method qualitative identification criteria, then then spiking level shall be increased and the initial MDL study pre-performed at the new spiking concentration.

19.9 Instrument Detection Limits (IDL)

The IDL is sometimes used to assess the reasonableness of the MDL or in some cases required by the analytical method or program requirements. IDLs are most commonly used in metals analyses but may be useful in demonstration of instrument performance in other areas.

IDLs are calculated to determine an instrument's sensitivity independent of any preparation method. IDLs are calculated either using 7 replicate spike analyses, like MDL but without sample preparation, or by the analysis of 10 instrument blanks and calculating 3 x the absolute value of the standard deviation.

19.10 Limit of Quantitation

The LOQ shall be at a concentration equivalent to the lowest calibration standard concentration, with the exception of methods using a single-point calibration, and shall be greater than the MDL. The LOQ is verified by preparing and analyzing spikes at concentrations 1-2X the selected LOQ, employing the complete analytical process.

When the laboratory establishes a quantitation limit, it must be initially verified by the analysis of a low level standard or QC sample at 1-2 times the reporting limit and annually thereafter. The annual requirement is waived for methods that have an annually verified MDL. The laboratory will comply with any regulatory requirements.

19.11 Retention Time Windows

Most organic analyses and some inorganic analyses use chromatography techniques for qualitative and quantitative determinations. For every chromatography analysis or as specified in the reference method, each analyte will have a specific time of elution from the column to the detector. This is known as the analyte's retention time. The variance in the expected time of elution is defined as the retention time window. As the key to analyte identification in chromatography, retention time windows must be established on every column for every analyte used for that method. These records are kept on-file and available for review. Complete details are available in the laboratory SOPs.

19.12 Evaluation of Selectivity

The laboratory evaluates selectivity by following the checks within the applicable analytical methods, which include mass spectral tuning, second column confirmation, ICP interelement interference checks, chromatography retention time windows, sample blanks, spectrochemical, atomic absorption or fluorescence profiles, and specific electrode response factors.

19.13 Estimation of Uncertainty of Measurement

19.13.1 Uncertainty is "a parameter associated with the result of a measurement, that characterizes the dispersion of the values that could reasonably be attributed to the measurement" (as defined by the International Vocabulary of Basic and General Terms in Metrology, ISO Geneva, 1993, ISBN 92-67-10175-1). Knowledge of the uncertainty of a measurement provides additional confidence in a result's validity. Its value accounts for all the factors which could possibly affect the result, such as adequacy of analyte definition, sampling, matrix effects and interferences, climatic conditions, variances in weights, volumes, and standards, analytical procedure, and random variation. Some national accreditation organizations require the use of an "expanded uncertainty" defined as the range within which the value of the measurand is believed to lie within at least a 95% confidence level with the coverage factor k=2.

19.13.2 Uncertainty is not error. Error is a single value (i.e., the difference between the true result and the measured result). On environmental samples, the true result is never known. The measurement is the sum of the unknown true value and the unknown error. Unknown error is a combination of systematic error, or bias, and random error. Bias varies predictably, constantly, and independently from the number of measurements. Random error is unpredictable, assumed to be Gaussian in distribution, and reducible by increasing the number of measurements.

19.13.3 The minimum uncertainty associated with results generated by the laboratory can be determined by using the Laboratory Control Sample (LCS) accuracy range for a given analyte. The LCS limits are used to assess the performance of the measurement system since they take into consideration all of the laboratory variables associated with a given test over time (except for variability associated with the sampling and the variability due to matrix effects). The percent recovery of the LCS is compared either to the method-required LCS accuracy limits or to the statistical, historical, in-house LCS accuracy limits.

19.13.4 To calculate the uncertainty for the specific result reported, multiply the result by the decimal of the lower end of the LCS range percent value for the lower end of the uncertainty range, and multiply the result by the decimal of the upper end of the LCS range percent value for the upper end of the uncertainty range. These calculated values represent uncertainties at approximately the 99% confidence level with a coverage factor of k = 3. As an example, for a reported result of 1.0 mg/L with an LCS recovery range of 50 to 150%, the estimated uncertainty in the result would be 1.0 +/- 0.5 mg/L.

19.13.5 In the case where a well-recognized test method specifies limits to the values of major sources of uncertainty of measurement (e.g., 524.2, 525, etc.) and specifies the form of presentation of calculated results, no further discussion of uncertainty is required.

19.14 Sample Reanalysis Guidelines

Because there is a certain level of uncertainty with any analytical measurement, a sample re-preparation (where appropriate) and subsequent analysis (hereafter referred to as 'reanalysis')

may result in either a higher or lower value from an initial sample analysis. There are also variables that may be present (e.g., sample homogeneity, analyte precipitation over time, etc.) that may affect the results of a reanalysis. Based on the above comments, the laboratory will reanalyze samples at a client's request with the following caveats. **Client specific Contractual Terms & Conditions for reanalysis protocols may supersede the following items.**

- Homogenous samples: If a reanalysis agrees with the original result to within the RPD limits for MS/MSD or Duplicate analyses, or within ± 1 reporting limit for samples ≤ 5x the reporting limit, the original analysis will be reported. At the client's request, both results may be reported on the same report but not on two separate reports.

- If the reanalysis does not agree (as defined above) with the original result, then the laboratory will investigate the discrepancy and reanalyze the sample a third time for confirmation if sufficient sample is available.

- Any potential charges related to reanalysis are discussed in the contract terms and conditions or discussed at the time of the request. The client will typically be charged for reanalysis unless it is determined that the lab was in error.

- Due to the potential for increased variability, reanalysis may not be applicable to Non-homogenous, Encore, and Sodium Bisulfate preserved samples. See the Area Supervisor *or* Laboratory Director if unsure.

19.15 Control of Data

The laboratory has policies and procedures in place to ensure the authenticity, integrity, and accuracy of the analytical data generated by the laboratory.

19.15.1 Computer and Electronic Data Related Requirements

The three basic objectives of our computer security procedures and policies are shown below. The laboratory is currently using the Eurofins LIMS system, which has been highly customized to meet the needs of the laboratory. It is referred to as LIMS for the remainder of this section.

19.15.1.1 Maintain the Database Integrity – Assurance that data is reliable and accurate through data verification (review) procedures, password-protecting access, anti-virus protection, data change requirements, as well as an internal LIMS permissions procedure.

- LIMS Database Integrity is achieved through data input validation, internal user controls, documentation of system failures and corrective actions taken, and data change requirements.
- Spreadsheets and other software developed in-house must be verified with documentation through hand calculations prior to use. Cells containing calculations must be lock-protected and controlled.
- Instrument hardware and software adjustments are safeguarded through maintenance logs, audit trails and controlled access.

19.15.1.2 Ensure Information Availability – Protection against loss of information or service is ensured through scheduled back-ups, stable file server network architecture, secure storage of media, line filter, Uninterruptible Power Supply (UPS), and maintaining older versions of software as revisions are implemented.

19.15.1.3 Maintain Confidentiality – Ensure data confidentiality through physical access controls such as password protection or website access approval when electronically transmitting data.

19.15.2 Data Reduction

The complexity of the data reduction depends on the analytical method and the number of discrete operations involved (e.g., extractions, dilutions, instrument readings and concentrations). The analyst calculates the final results from the raw data or uses appropriate computer programs to assist in the calculation of final reportable values.

For manual data entry, e.g., Wet Chemistry, the data is reduced by the analyst and then verified by the Group Leader or alternate analyst once the data is uploaded or entered into LIMS. The spreadsheets, or any other type of applicable documents, are initialed by both the analyst and alternate reviewer to confirm the accuracy of the manual entry(s).

Manual integration of peaks will be documented and reviewed and the raw data will be flagged using NDSG Document No. CA-Q-S-002, *Acceptable Manual Integration Practices*.

Analytical results are reduced to appropriate concentration units specified by the analytical method, taking into account factors such as dilution, sample weight or volume, etc. Blank correction will be applied only when required by the method or per manufacturer's indication; otherwise, it should not be performed. Calculations are independently verified by appropriate laboratory staff. Calculations and data reduction steps for various methods are summarized in the respective analytical SOPs or program requirements.

19.15.2.1 All raw data must be retained in the worklist folder, computer file (if appropriate), and/or run log. All criteria pertinent to the method must be recorded. The documentation is recorded at the time observations or calculations are made and must be signed or initialed/dated (month/day/year). It must be easily identifiable who performed which tasks if multiple people were involved.

19.15.2.2 In general, concentration results are reported in milligrams per liter (mg/l) or micrograms per liter (µg/l) for liquids and milligrams per kilogram (mg/kg) or micrograms per kilogram (µg/kg) for solids. For values greater than 10,000 mg/l, results can be reported in percent, i.e., 10,000 mg/l = 1**%.** Units are defined in each lab SOP.

19.15.2.3 In reporting, the analyst or the instrument output records the raw data result using values of known certainty plus one uncertain digit. If final calculations are performed external to LIMS, the results should be entered in LIMS with at least three significant figures. In general, results are reported to 2 significant figures on the final report.

19.15.2.4 For those methods that do not have an instrument printout or an instrumental output compatible with the LIMS System, the raw results and dilution factors are entered directly into LIMS by the analyst, and the software calculates the final result for the analytical report. LIMS has a formatter for significant figure criterion for each analyte.

19.15.2.5 The laboratory strives to import data directly from instruments or calculation spreadsheets to ensure that the reported data are free from transcription and calculation errors. For those analyses with an instrumental output compatible with the LIMS, the raw results and dilution factors are transferred into LIMS electronically after reviewing the quantitation report, and removing unrequested or poor spectrally-matched compounds. The analyst prints a copy of what has been entered to check for errors. This printout and the instrument's printout of calibrations, concentrations, retention times, chromatograms, and mass spectra, if applicable, are retained with the data file. The data file is stored in a monthly folder on the instrument computer; periodically, this file is transferred to the server and, eventually, to a tape file.

19.15.3 Logbook / Worksheet Use Guidelines

Logbooks and worksheets are filled out 'real time' and have enough information on them to trace the events of the applicable analysis/task. (e.g. calibrations, standards, analyst, sample ID, date, time on short holding time tests, temperatures when applicable, calculations are traceable, etc.)

- Corrections are made following the procedures outlined in Section 14.
- Logbooks are controlled by the QA department. A record is maintained of all logbooks in the lab.
- Unused portions of worksheet pages must be "Z"'d out, signed and dated. Logbooks with unused pages: The first unused page will be Z'd out, signed, and dated. A note will be added to this page stating that the logbook has been closed and no further pages are to be used.
- Worksheets are created with the approval of the QA Manager or designee at the facility. The QA Manager or designee controls all worksheets following the procedures in Section 6.

19.15.4 Review / Verification Procedures

Review procedures are outlined in several SOPs to ensure that reported data are free from calculation and transcription errors, that QC parameters have been reviewed and evaluated before data is reported. The laboratory also has an SOP discussing Manual Integrations to ensure the authenticity of the data. The general review concepts are discussed below, more specific information can be found in the SOPs.

19.15.4.1 Log-In Review - The data review process starts at the sample receipt stage. Sample control personnel review chain-of-custody forms and project instructions from the project management group. This is the basis of the sample information and analytical instructions entered into the LIMS. The log-in instructions are reviewed by the personnel entering the information, and a second level review is conducted by the project management staff.

19.15.4.2 First Level Data Review - The next level of data review occurs with the analysts. As data are generated, analysts review their work to ensure that the results meet project and SOP requirements. First level reviews include inspection of all raw data (e.g., instrument output for continuous analyzers, chromatograms, spectra, and manual integrations), evaluation of calibration/calibration verification data in the day's analytical run, evaluation of QC data, and reliability of sample results. The analyst transfers data into LIMS, data qualifiers are added as needed. All first level reviews are documented.

19.15.4.3 Second Level Data Review – All analytical data are subject to review by a second qualified analyst or supervisor. Second level reviews include inspection of all raw data (e.g., instrument output, chromatograms, and spectra) including 100% of data associated with any changes made by the primary analyst, such as manual integrations or reassignment of peaks to different analytes, or elimination of false negative analytes. The second review also includes evaluation of initial calibration/calibration verification data in the day's analytical run, evaluation of QC data, reliability of sample results, verification of units vs matrix, qualifiers and NCM narratives. Manual calculations are checked in second level review. All second level reviews are documented.

Issues that deem further review include the following:

- QC data are outside the specified control limits for accuracy and precision
- Reviewed sample data does not match with reported results
- Unusual detection limit changes are observed
- Samples having unusually high results
- Samples exceeding a known regulatory limit
- Raw data indicating some type of contamination or poor technique
- Inconsistent peak integration
- Transcription errors
- Results outside of calibration range

19.15.4.4 Unacceptable analytical results may require reanalysis of the samples. Any problems are brought to the attention of the Laboratory Director, Project Manager, Quality Director/Manager, Technical Director, or Supervisor for further investigation. Corrective action is initiated whenever necessary.

19.15.4.5 The results are then entered or directly transferred into the computer database and a hard copy (or .pdf) is printed for the client.

19.15.4.6 As a final review prior to the release of the report, the Project Manager reviews the results for appropriateness and completeness. This review and approval ensures that client requirements have been met and that the final report has been properly completed. The process includes, but is not limited to, verifying that the COC is followed, cover letters / narratives are present, flags are appropriate, reported units are appropriate for the sample matrix, and project specific requirements are met. The Project Manager may also evaluate the validity of results for different test methods given expected chemical relationships.

19.15.4.7 Any project that requires a data package is subject to a tertiary data review for transcription errors and acceptable quality control requirements. The Project Manager then electronically signs the final report which is sent out to the client.

19.15.4.8 A brief overview of sample flows and information through the laboratory, as well as data review and validation, is presented in Figure 19-1.

19.15.5 Manual Integrations

Computerized data systems provide the analyst with the ability to re-integrate raw instrument data in order to optimize the interpretation of the data. Though manual integration of data is an invaluable tool for resolving variations in instrument performance and some sample matrix problems, when used improperly, this technique would make unacceptable data appear to meet quality control acceptance limits. Improper re-integrations lead to legally indefensible data, a poor reputation, or possible laboratory decertification. Because guidelines for re-integration of data are not provided in the methods and most methods were written prior to widespread implementation of computerized data systems, the laboratory trains all analytical staff on proper manual integration techniques using NDSC Document No. CA-Q-S-002 Acceptable Manual Integration Practices.

19.15.5.1 The analyst must adjust baseline or the area of a peak in some situations, for example when two compounds are not adequately resolved or when a peak shoulder needs to be separated from the peak of interest. The analyst must use professional judgment to determine when manual integrating is required. Analysts are encouraged to ask for assistance from a senior analyst or manager when in doubt.

19.15.5.2 Analysts shall not increase or decrease peak areas for the sole purpose of achieving acceptable QC recoveries that would have otherwise been unacceptable. The intentional recording or reporting of incorrect information (or the intentional omission of correct information) is against company principles and policy and is grounds for immediate termination.

19.15.5.3 Client samples, performance evaluation samples, and quality control samples are all treated equally when determining whether or not a peak area or baseline should be manually adjusted.

19.15.5.4 All manual integrations receive a second level review. Manual integrations must be indicated on expanded scale “before” and “after” chromatograms such that the integration performed can be easily evaluated during data review. Expanded scale “before” chromatograms are also required for all manual integrations on QC parameters (calibrations, calibration verifications, laboratory control samples, internal standards, surrogates, etc.) unless the laboratory has another documented NDSC approved procedure in place that can demonstrate an active process for detection and deterrence of improper integration practices.

Figure 19-1. Example: Work Flow

Action	Personnel Involved
Bottle orders generated upon request - Bottles packed and shipped to the client under CoC	- Client Service Personnel / PM - Bottle Preparation Personnel
Samples received at laboratory - Unpacked and reconciled against client paperwork or CoC - Samples acceptance documented against completed (CoC)[1]	Sample Login Personnel
Samples are entered into LIMS - Job # assigned - Methods/Analytes linked from project - Sample labels generated - LIMS backlogs updated immediately	Sample Login Personnel
Sample Storage - Short TATs and hold-time samples are delivered directly to the laboratory for analysis - Samples stored in assigned locations (refrigerated walk-in coolers, freezers, VOA refrigerators; etc.)	Sample Login Personnel
Sample Receipt Acknowledgement sent to client (when requested)	Sample Login Personnel
Sample Acquisition/Testing - Analysts collect samples from assigned storage. - Legal CoC samples are signed in-and-out of storage - Remaining sample returned to storage.	Analysts / Login Personnel
Preparation and analysis is performed according to selected analytical method and applicable Project notes - Raw data recorded/reviewed[2] - Data imported to LIMS	Analysts
LIMS performs calculations: - Data reviewed by primary/secondary analyst - Data approved as final	Data Process (LIMS / Analyst)
Generation/review/release of reports (automated through LIMS) - Electronic copy saved in LIMS	Project Management Assistants / Reporting Group
Electronic Data Deliverables (EDDs) generated (as applicable)	EDD Group
Hard copy and electronic batch raw data is archived according to data archiving procedures.	Analysts / IT

[1]Refer to Sec. 23.3.
[2]Analyses requiring the analyst's interpretation may involve manual data reduction before entry.

SECTION 20. EQUIPMENT and CALIBRATIONS

20.1 Overview

The laboratory purchases the most technically advanced analytical instrumentation for sample analyses. Instrumentation is purchased on the basis of accuracy, dependability, efficiency and sensitivity. Each laboratory is furnished with all items of sampling, preparation, analytical testing and measurement equipment necessary to correctly perform the tests for which the laboratory has capabilities. Each piece of equipment is capable of achieving the required accuracy and complies with specifications relevant to the method being performed. Before being placed into use, the equipment (including sampling equipment) is calibrated and checked to establish that it meets its intended specification. The calibration routines for analytical instruments establish the range of quantitation. Calibration procedures are specified in laboratory SOPs. A list of available laboratory instrumentation is presented in Table 20-1.

Equipment is only operated by authorized and trained personnel. Manufacturer's instructions for equipment use are readily accessible to all appropriate laboratory personnel.

20.2 Preventive Maintenance

The laboratory follows a well-defined maintenance program to ensure proper equipment operation and to prevent the failure of laboratory equipment or instrumentation during use. This program of preventive maintenance helps to avoid delays due to instrument failure.

Routine preventive maintenance procedures and frequency, such as cleaning and replacements, should be performed according to the procedures outlined in the manufacturer's manual. Qualified personnel must also perform maintenance when there is evidence of degradation of peak resolution, a shift in the calibration curve, loss of sensitivity, or failure to continually meet one of the quality control criteria.

Scheduled routine maintenance is defined in each method SOP. It is the responsibility of each Group Leader to ensure that instrument maintenance logs are kept for all equipment in his/her department. Preventative maintenance procedures are also outlined in analytical SOPs and/or instrument manuals. (**Note:** for some equipment, the log used to monitor performance is also the maintenance log. Multiple pieces of equipment may share the same log as long as it is clear as to which instrument is associated with an entry.)

Instrument maintenance logs are controlled and are used to document instrument problems, instrument repair and maintenance activities. Maintenance logs shall be kept for all major pieces of equipment. Instrument maintenance logs may also be used to specify instrument parameters.

- Documentation must include all major maintenance activities such as contracted preventive maintenance and service and in-house activities such as the replacement of electrical components, lamps, tubing, valves, columns, detectors, cleaning and adjustments.
- Each entry in the instrument log includes the analyst's initials, the date, a detailed description of the problem (or maintenance needed/scheduled), a detailed explanation of the solution or maintenance performed, and a verification that the equipment is functioning properly (state what was used to determine a return to control. e.g. CCV run on *'date'* was acceptable, or

instrument recalibrated on 'date' with acceptable verification, etc.) must also be documented in the instrument records.

- When maintenance or repair is performed by an outside agency, service receipts detailing the service performed can be affixed into the logbooks adjacent to pages describing the maintenance performed. This stapled in page must be signed across the page entered and the logbook so that it is clear that a page is missing if only half a signature is found in the logbook.

If an instrument requires repair (subjected to overloading or mishandling), gives suspect results, or otherwise has shown to be defective or outside of specified limits it shall be taken out of operation and tagged as out-of-service or otherwise isolated until such a time as the repairs have been made and the instrument can be demonstrated as operational by calibration and/or verification or other test to demonstrate acceptable performance. The laboratory shall examine the effect of this defect on previous analyses.

In the event of equipment malfunction that cannot be resolved, service shall be obtained from the instrument vendor manufacturer, or qualified service technician, if such a service can be tendered. If on-site service is unavailable, arrangements shall be made to have the instrument shipped back to the manufacturer for repair. Back up instruments, which have been approved, for the analysis shall perform the analysis normally carried out by the malfunctioning instrument. If the back-up is not available and the analysis cannot be carried out within the needed timeframe, the samples shall be subcontracted.

At a minimum, if an instrument is sent out for service or transferred to another facility, it must be recalibrated and the laboratory MDL verified (using an MDLV) prior to return to lab operations.

20.3 Support Equipment

This section applies to all devices that may not be the actual test instrument, but are necessary to support laboratory operations. These include but are not limited to: balances, ovens, refrigerators, freezers, incubators, water baths, field sampling devices, temperature measuring devices, thermal/pressure sample preparation devices and volumetric dispensing devices if quantitative results are dependent on their accuracy, as in standard preparation and dispensing or dilution into a specified volume. All raw data records associated with the support equipment are retained to document instrument performance.

20.3.1 Weights and Balances

The accuracy of the balances used in the laboratory is checked every working day, before use. All balances are placed on stable counter tops.

Each balance is checked prior to initial serviceable use with at least two certified ASTM type 1 weights spanning its range of use (weights that have been calibrated to ASTM type 1 weights may also be used for daily verification). ASTM type 1 weights used only for calibration of other weights (and no other purpose) are inspected for corrosion, damage or nicks at least annually and if no damage is observed, they are calibrated at least every 5 years by an outside calibration laboratory. Any weights (including ASTM Type 1) used for daily balance checks or other purposes are recalibrated/recertified annually to NIST standards (this may be done internally if laboratory maintains "calibration only" ASTM type 1 weights).

All balances are serviced annually by a qualified service representative, who supplies the laboratory with a certificate that identifies traceability of the calibration to the NIST standards.

All of this information is recorded in logs, and the recalibration/recertification certificates are kept on file. Further details on balance calibrations and verifications can be found in SOP NC-QA-015 Support Equipment Calibration and Verification.

20.3.2 pH, Conductivity, and Turbidity Meters

The pH meters used in the laboratory are accurate to ± 0.1 pH units, and have a scale readability of at least 0.05 pH units. The meters automatically compensate for the temperature, and are calibrated with at least two working range buffer solutions before each use.

Conductivity meters used in the laboratory are capable of measuring conductivity with an error not exceeding 1% or one umhos/cm, whichever is greater. The meters are also calibrated before each use with a known standard.
Turbidity meters are also calibrated before each use. All of this information is documented in logs.

Consult pH, Conductivity, and Turbidity SOPs for further information.

20.3.3 Thermometers

All liquid in glass thermometers are calibrated on an annual basis with a NIST-traceable thermometer.

- If the temperature measuring device is used over a range of 10°C or less, then a single point verification within the range of use is acceptable;
- If the temperature measuring device is used over a range of greater than 10°C, then the verification must bracket the range of use.

IR thermometers, digital probes and thermocouples are calibrated quarterly.

The digital NIST thermometer is recalibrated every year (unless thermometer has been exposed to temperature extremes) by an approved outside service and the provided certificate of traceability is kept on file. The NIST thermometer(s) have increments of 0.01 degree (0.5 degree or less increments are required for drinking water microbiological laboratories), and have ranges applicable to method and certification requirements. The NIST traceable thermometer is used for no other purpose than to calibrate other thermometers.

All of this information is documented in spreadsheets, logsheets, and/or electronically. Monitoring method-specific temperatures, including incubators, heating blocks, water baths, and ovens, is documented on unit specific logsheets or in LIMS. More information on this subject can be found in SOP No. NC-QA-015 Support Equipment Calibration and Verification.

20.3.4 Refrigerators/Freezer Units, Water baths, Ovens and Incubators

The temperatures of all refrigerator units and freezers used for sample and standard storage are monitored each working day.

Ovens, water baths and incubators are monitored on days of use.

All of this equipment has a unique identification number, and is assigned a thermometer/continuous monitoring sensor for monitoring.

Sample storage refrigerator temperatures are kept between > 0ºC and ≤ 6 ºC.

Specific temperature settings/ranges for other refrigerators, ovens, water baths, and incubators can be found in method specific SOPs.

All of this information is documented on Daily Temperature Logsheets and/or electronically via LIMS or the Temperature Guard System and discussed in SOP No. NC-QA-015 Support Equipment Calibration and Verification.

20.3.5 Autopipettors, Dilutors, and Syringes

Mechanical volumetric dispensing devices including burettes (except Class A Glassware) and syringes are given unique identification numbers and the delivery volumes are verified gravimetrically, at a minimum, on a quarterly basis.

For those dispensers that are not used for analytical measurements, a label shall be applied to the device stating that it is not calibrated. Any device not regularly verified cannot be used for any quantitative measurements.

Micro-syringes are purchased from Hamilton Company. Each syringe is traceable to NIST. The laboratory keeps on file an “Accuracy and Precision Statement of Conformance” from Hamilton attesting established accuracy and considers the statement valid for the first six months. After six months, syringes that dispense volumes greater than 20 uL must be verified or replaced.

20.3.6 Field Sampling Devices (ISCO Auto Samplers)

Each Auto Sampler (ISCO) is assigned a unique identification number in order to keep track of the calibration. This number is also recorded on the sampling documentation.

The Auto Sampler is calibrated semiannually or as needed by setting the sample volume to 100ml and recording the volume received. The results are filed in a logbook/binder. The Auto Sampler is programmed to run three (3) cycles and each of the three cycles is measured into a graduated cylinder to verify 100ml are received.

If the RSD (Relative Standard Deviation) between the 3 cycles is greater than 20%, the procedure is repeated and if the result is still greater than 20%, then the Auto Sampler is taken out of service until it is repaired and calibration verification criteria can be met. The results of this check are kept in a logbook/binder.

20.4 Instrument Calibrations

Calibration of analytical instrumentation is essential to the production of quality data. Strict calibration procedures are followed for each method. These procedures are designed to

determine and document the method detection limits, the working range of the analytical instrumentation and any fluctuations that may occur from day to day.

Sufficient raw data records are retained to allow an outside party to reconstruct all facets of the initial calibration. Records contain, but are not limited to, the following: calibration date, method, instrument, analyst(s) initials or signatures, analysis date, analytes, concentration, response, and type of calibration (Avg RF, curve, or other calculations that may be used to reduce instrument responses to concentration.)

Sample results must be quantitated from the initial calibration and may not be quantitated from any continuing instrument calibration verification unless otherwise required by regulation, method or program.

If the initial calibration results are outside of the acceptance criteria, corrective action is performed and any affected samples are reanalyzed if possible. If the reanalysis is not possible, any data associated with an unacceptable initial calibration will be reported with appropriate data qualifiers (refer to Section 12).

Note: Instruments are calibrated initially and as needed after that and at least annually.

20.4.1 Calibration Standards

Calibration standards are prepared using the procedures indicated in the Reagents and Standards section of the determinative method SOP. If a reference method does not specify the number of calibration standards, a minimum number of calibration points as defined by the type of calibration curve. will be used.

Standards for instrument calibration are obtained from a variety of sources. All standards are traceable to national or international standards of measurement, or to national or international standard reference materials.

The lowest concentration calibration standard that is analyzed during an initial calibration must be at or below the stated reporting limit for the method based on the final volume of extract (or sample).

The other concentrations define the working range of the instrument/method or correspond to the expected range of concentrations found in actual samples that are also within the working range of the instrument/method. Results of samples not bracketed by initial instrument calibration standards (within calibration range to at least the same number of significant figures used to report the data) must be reported as having less certainty, e.g., defined qualifiers or flags (additional information may be included in the case narrative). The exceptions to these rules. ICP and ICPMS methods which define the working range with periodic linear dynamic range studies, rather than through the range of concentrations of daily calibration standards.

All initial calibrations are verified with a standard obtained from a second source and traceable to a national standard, when available (or vendor certified different lot if a second source is not available). For unique situations, where no other source or lot is available, a standard made by a different analyst at a different time or a different preparation would be considered a second

source. This verification occurs immediately after the calibration curve has been analyzed, and before the analysis of any samples.

20.4.1.1 Calibration Verification

The calibration relationship established during the initial calibration must be verified initially and at least daily as specified in the laboratory method SOPs in accordance with the referenced analytical methods and in the 2009 and 2016 TNI Standard. The process of calibration verification applies to both external standard and internal standard calibration techniques, as well as to linear and non-linear calibration models. Initial calibration verification (ICV) is with a standard source secondary (second source standard) to the calibration standards, but continuing calibration verifications (CCV) may use the same source standards as the calibration curve.

Note: The process of calibration verification referred to here is fundamentally different from the approach called "calibration" in some methods. As described in those methods, the calibration factors or response factors calculated during calibration are used to update the calibration factors or response factors used for sample quantitation. This approach, while employed in other EPA programs, amounts to a daily single-point calibration.

All target analytes and surrogates, including those reported as non-detects, must be included in periodic calibration verifications for purposes of retention time confirmation and to demonstrate that calibration verification criteria are being met, i.e., RPD, per 2009 and 2016 TNI Std. EL-V1M4 Sec. 1.7.2.

All samples must be bracketed by periodic analyses of standards that meet the QC acceptance criteria (e.g., calibration and retention time). The frequency is found in the determinative methods or SOPs.

Note: If an internal standard calibration is being used then bracketing calibration verification standards may not be required, only daily verifications are needed. The results from these verification standards must meet the calibration verification criteria and the retention time criteria (if applicable).

Generally, the calibrations must be verified by an ICV analyzed immediately following initial calibration and before sample analysis. The ICV may be used as the first bracketing CCV, if criteria for both are met.

A continuing instrument calibration verification (CCV) is generally analyzed at the beginning of each 12-hour analytical shift during which samples are analyzed. The 12-hour analytical shift begins with the injection of the calibration verification standard (or the MS tuning standard in MS methods). The shift ends after the completion of the analysis of the last sample, QC, or standard that can be injected within 12-hours of the beginning of the shift. For methods that have quantitation by external calibration models, a CCV is analyzed at the end of each analytical sequence. Some methods have more frequent CCV requirements. See specific SOPs. Most inorganic methods require the CCV to be analyzed after ever 10 samples or injections, including matrix or batch QC samples.

Note: If an internal standard calibration is being used (e.g., GCMS) then bracketing standards are not required, only daily verifications are needed, except as specified by program or method requirements.

If the results of a CCV are outside the established acceptance criteria and analysis of a second consecutive (and immediate) CCV fails to produce results within acceptance criteria, corrective action shall be performed. Once corrective actions have been completed and documented, the laboratory shall demonstrate acceptable instrument / method performance by analyzing two consecutive CCVs, or a new initial instrument calibration shall be performed.

Sample analyses and reporting of data may not occur or continue until the analytical system is calibrated or calibration verified. However, data associated with an unacceptable calibration verification may be fully useable reported based upon discussion and approval of the client under the following special conditions:

a). when the acceptance criteria for the CCV are exceeded high (i.e., high bias) and the associated samples within the batch are non-detects, then those non-detects may be reported with a case narrative comment explaining the high bias. Otherwise the samples affected by the unacceptable CCV shall be re-analyzed after a new calibration curve has been established, evaluated and accepted; or

b). when the acceptance criteria for the CCV are exceeded low (i.e., low bias), those sample results may be reported if they exceed a maximum regulatory limit/decision level. Otherwise the samples affected by the unacceptable CCV shall be re-analyzed after a new calibration curve has been established, evaluated and accepted.

Samples reported by the 2 conditions identified above will be appropriately flagged.

20.4.1.2 Verification of Linear and Non-Linear Calibrations

Calibration verification for calibrations involves the calculation of the percent drift or the percent difference of the instrument response between the initial calibration and each subsequent analysis of the verification standard. (These calculations are available in the laboratory method SOPs.) Verification standards are evaluated based on the % Difference from the average CF or RF of the initial calibration or based on % Drift or % Recovery if a linear or quadratic curve is used.

Regardless of whether a linear or non-linear calibration model is used, if initial verification criterion is not met, then no sample analyses may take place until the calibration has been verified or a new initial calibration is performed that meets the specifications listed in the method SOPs. If the calibration cannot be verified after the analysis of a single verification standard, then adjust the instrument operating conditions and/or perform instrument maintenance, and analyze another aliquot of the verification standard. If the calibration cannot be verified with the second standard, then a new initial calibration is performed.

- When the acceptance criteria for the calibration verification are exceeded high, i.e., high bias, and there are associated samples that are non-detects, then those non-detects may be reported. Otherwise, the samples affected by the unacceptable calibration verification shall be reanalyzed after a new calibration curve has been established, evaluated and accepted.

- When the acceptance criteria for the calibration verification are exceeded low, i.e., low bias, those sample results may be reported if they exceed a maximum regulatory limit/decision level. Otherwise, the samples affected by the unacceptable verification shall be reanalyzed after a new calibration curve has been established, evaluated and accepted. Alternatively, a reporting limit standard may be analyzed to demonstrate that the laboratory can still support non-detects at their reporting limit. For Ohio VAP samples, results may not be reported when calibration verifications fail the lower limit criterion.

20.5 Tentatively Identified Compounds (TICs) – GC/MS Analysis

For samples containing components not associated with the calibration standards, a library search may be made for the purpose of tentative identification. The necessity to perform this type of identification will be determined by the purpose of the analyses being conducted. For example, the RCRA permit or waste delisting requirements may require the reporting of non-target analytes. Only after visual comparison of sample spectra with the nearest library searches may the analyst assign a tentative identification. Data system library search routines should not use normalization routines that would misrepresent the library or unknown spectra when compared to each other. Additional details are provided in NDSC Document No. CA-Q-QM-001, Tentatively Identified Compounds (TICS) - GCMS Analysis

Note: If the TIC compound is not part of the client target analyte list but is calibrated by the laboratory and is both qualitatively and/or quantitatively identifiable, it should not be reported as a TIC. If the compound is reported on the same form as true TICs, it should be qualified and/or narrated that the reported compound is qualitatively and quantitatively (if verification in control) reported compared to a known standard that is in control (where applicable).

20.6 GC/MS Tuning

Prior to any GC/MS analytical sequence, including calibration, the instrument parameters for the tune and subsequent sample analyses within that sequence must be set.

Prior to tuning/auto-tuning the mass spectrometer, the parameters may be adjusted within the specifications set by the manufacturer or the analytical method. These generally do not need any adjustment but it may be required based on the current instrument performance. If the tune verification does not pass it may be necessary to clean the source or perform additional maintenance. Any maintenance is documented in the maintenance log.

Note: Laboratory instrumentation, model numbers, and serial numbers are subject to change without notice.

SECTION 21. MEASUREMENT TRACEABILITY

21.1 Overview

Traceability of measurements shall be assured using a system of documentation, calibration, and analysis of reference standards. Laboratory equipment that are peripheral to analysis and whose calibration is not necessarily documented in a test method analysis or by analysis of a reference standard shall be subject to ongoing certifications of accuracy. At a minimum, these must include procedures for checking specifications of ancillary equipment: balances, thermometers, temperature, Deionized (DI) and Reverse Osmosis (RO) water systems, automatic pipettes and other volumetric measuring devices. (Refer to Section 20.3). With the exception of Class A Glassware, quarterly accuracy checks are performed for all mechanical volumetric devices. Micro syringes used to dispense volumes greater than 20 uL are verified at least semi-annually or disposed of after 6 months of use. Wherever possible, subsidiary or peripheral equipment is checked against standard equipment or standards that are traceable to national or international standards. Class A Glassware should be routinely inspected for chips, acid etching or deformity (e.g., bent needle). If the Class A glassware is suspect, the accuracy of the glassware will be assessed prior to use.

21.2 NIST-Traceable Weights and Thermometers

Reference standards of measurement shall be used for calibration only and for no other purpose, unless it can be shown that their performance as reference standards would not be invalidated.

For NIST-traceable weights and thermometers, the laboratory requires that all calibrations be conducted by a calibration laboratory accredited by A2LA, NVLAP (National Voluntary Laboratory Accreditation Program), or another accreditation organization that is a signatory to a MRA (Mutual Recognition Arrangement) of one or more of the following cooperations – ILAC (International Laboratory Accreditation Cooperation) or APLAC (Asia–Pacific Laboratory Accreditation Cooperation). A calibration certificate and scope of accreditation is kept on file at the laboratory.

21.3 Reference Standards / Materials

Reference standards/materials, where commercially available, are traceable to certified reference materials. Commercially prepared reference standards, to the extent available, are purchased from vendors that are accredited to ISO Guide 34 and ISO/IEC Guide 17025. All reference standards from commercial vendors shall be accompanied with a certificate that includes at least the following information:

- Manufacturer
- Analytes or parameters calibrated
- Identification or lot number
- Calibration method
- Concentration with associated uncertainties
- Purity

If a standard cannot be purchased from a vendor that supplies a Certificate of Analysis, the purity of the standard is documented by analysis. The receipt of all reference standards must be documented. Reference standards are labeled with a unique standard identification number and

expiration date. All documentation received with the reference standard is retained as a QC record and references the standard identification number.

All reference, primary and working standards/materials, whether commercially purchased or laboratory prepared, must be checked regularly to ensure that the variability of the standard or material from the true value does not exceed method requirements. The accuracy of calibration standards is checked by comparison with a standard from a second source. In cases where a second standard manufacturer is not available, a vendor certified different lot is acceptable for use as a second source. For unique situations, where no other source or lot is available, a standard made by a different analyst would be considered a second source. The appropriate Quality Control (QC) criteria for specific standards are defined in laboratory SOPs. In most cases, the analysis of an Initial Calibration Verification (ICV) or LCS (where there is no sample preparation) is used as the second source confirmation. These checks are generally performed as an integral part of the analysis method (e.g. calibration checks, laboratory control samples).

All standards and materials must be stored and handled according to method or manufacturer's requirements in order to prevent contamination or deterioration. Refer to the Environmental Health & Safety Manual or laboratory SOPs. For safety requirements, please refer to method SOPs and the laboratory's Environmental Health and Safety Manual.

Standards and reference materials shall not be used after their expiration dates unless their reliability is verified by the laboratory and their use is approved by the Quality Assurance Manager. The laboratory must have documented contingency procedures for re-verifying expired standards.

21.4 Documentation and Labeling of Standards, Reagents, and Reference Materials

Reagents must be at a minimum the purity required in the test method. The date of reagent receipt and the expiration date are documented. The lots for most of the common solvents and acids are tested for acceptability prior to company-wide purchase. [Refer to NDSC Document No. CA-Q-S-001 Solvent and Acid Lot Testing and Approval

All manufacturer or vendor supplied Certificate of Analysis or Purity must be retained, stored appropriately, and readily available for use and inspection. These records are maintained in LIMS or in binders in the laboratory departments. Records must be kept of the date of receipt and date of expiration of standards, reagents and reference materials. In addition, records of preparation of laboratory standards, reagents, and reference materials must be retained, stored appropriately, and be readily available for use and inspection. For detailed information on documentation and labeling, please refer to SOP NC-QA-017 Standards and Reagents.

Commercial materials purchased for preparation of calibration solutions, spike solutions, etc.., are usually accompanied with an assay certificate or the purity is noted on the label. If the assay purity is 96% or better, the weight provided by the vendor may be used without correction. If the assay purity is less than 96% a correction will be made to concentrations applied to solutions prepared from the stock commercial material. Blended gas standard cylinders use a nominal concentration if the certified value is within +/-15%, otherwise the certified values is used for the canister concentration.

21.4.1 All standards, reagents, and reference materials must be labeled in an unambiguous manner. Standards are logged into the laboratory's LIM system, and are assigned a unique identification number. The following information is typically recorded in the electronic database within the LIMS.

- Standard ID
- Description of Standard
- Department
- Preparer's name
- Final volume and number of vials prepared
- Solvent type and lot number
- Preparation Date
- Expiration Date
- Standard source type (stock or daughter)
- Standard type (spike, surrogate, other)
- Parent standard ID (if applicable)
- Parent Standard Analyte Concentration (if applicable)
- Parent Standard Amount used (if applicable)
- Component Analytes
- Final concentration of each analyte
- Comment box (text field)

Records are maintained electronically for standard and reference material preparation. These records show the traceability to purchased stocks or neat compounds. These records also include method of preparation, date of preparation, expiration date and preparer's name or initials. Preparation procedures are provided in the Method SOPs.

21.4.2 All standards, reagents, and reference materials must be clearly labeled with a minimum of the following information:

- Expiration Date (include prep date for reagents)
- Standard ID from LIMS
- Special Health/Safety warnings if applicable

Records must also be maintained of the date of receipt for commercially purchased items or date of preparation for laboratory prepared items. Special Health/Safety warnings must also be available to the analyst. This information is maintained in the analytical SOPs.

21.4.3 In addition, the following information may be helpful:

- Date opened (for multi-use containers, if applicable)
- Description of standard (if different from manufacturer's label or if standard was prepared in the laboratory)
- Recommended Storage Conditions

- Concentration (if applicable)
- Initials of analyst preparing standard or opening container

All containers of prepared reagents must include an expiration date and an ID number to trace back to preparation.

Procedures for preparation of reagents can be found in the Method SOPs.

Standard ID numbers must be traceable through associated logbooks, worksheets and preparation/analytical batch records.

All reagents and standards must be stored in accordance to the following priority: 1) with the manufacturer's recommendations; 2) with requirements in the specific analytical methods as specified in the laboratory SOP.

SECTION 22. SAMPLING

22.1 Overview

The laboratory provides sampling services. Sampling procedures are described in SOP NC-SC-006, Sample Procurement Protocol.

22.2 Sampling Containers

The laboratory offers clean sampling containers for use by clients. These containers are obtained from reputable container manufacturers and meet EPA specifications as required. Certificates of cleanliness for bottles and preservatives are provided by the supplier and are maintained at the laboratory. Alternatively, the certificates may be maintained by the supplier and available to the laboratory on-line.

22.2.1 Preservatives

Upon request, preservatives are provided to the client in pre-cleaned sampling containers. In some cases containers may be purchased pre-preserved from the container supplier. Whether prepared by the laboratory or bought pre-preserved, the grades of the preservatives are at a minimum:

- Hydrochloric Acid – Reagent ACS (Certified VOA Free) or equivalent
- Methanol – Purge and Trap grade
- Nitric Acid – Instra-Analyzed or equivalent
- Sodium Bisulfate – ACS Grade or equivalent
- Sodium Hydroxide – Instra-Analyzed or equivalent
- Sulfuric Acid – Instra-Analyzed or equivalent
- Sodium Thiosulfate – ACS Grade or equivalent

22.3 Definition of Holding Time

The date and time of sampling documented on the COC form establishes the day and time zero. As a general rule, when the maximum allowable holding time is expressed in days (e.g., 14 days, 28 days), the holding time is based on calendar day measured. Holding times expressed in hours (e.g., 6 hours, 24 hours, etc.) are measured from date and time zero. Holding times for analysis include any necessary reanalysis. However, there are some programs that determine holding time compliance based on the date and specific time of analysis compared to the time of sampling regardless of how long the holding time is.

22.4 Sampling Containers, Preservation Requirements, Holding Times

The preservation and holding time criteria specified in the laboratory SOPs are derived from the source documents for the methods. If method required holding times or preservation requirements are not met, the reports will be qualified using a flag, footnote or case narrative. As soon as possible or "ASAP" is an EPA designation for tests for which rapid analysis is advised, but for which neither EPA nor the laboratory have a basis for a holding time.

22.5 Sample Aliquots / Subsampling

Taking a representative sub-sample from a container is necessary to ensure that the analytical results are representative of the sample collected in the field. The size of the sample container, the quantity of sample fitted within the container, and the homogeneity of the sample need consideration when sub-sampling for sample preparation. It is the laboratory's responsibility to take a representative subsample or aliquot of the sample provided for analysis.

Analysts should handle each sample as if it is potentially dangerous. At a minimum, safety glasses, gloves, and lab coats must be worn when preparing aliquots for analysis.

Guidelines on taking sample aliquots and subsampling are located in each analytical SOP and in Subsampling SOP NC-OP-046.

23 HANDLING OF SAMPLES

It is the responsibility of the client to send us representative and/or homogeneous and properly preserved samples of the system from which they are drawn. The laboratory assumes that all multiple sample containers with the same designator/description and bottle type contain a homogeneous, representative sample.

The laboratory provides the appropriate sample containers, required preservative, chain-of-custody (COC) forms, shipping containers, labels, and custody seals. The laboratory also provides trip blanks and analyte-free water for field blanks. Preparation of methanol containers for field preservation of volatile soil samples is available.

Sample management procedures at the laboratory ensure that sample integrity and custody are maintained and documented from sampling/receipt through disposal.

23.1 Chain of Custody (COC)

The COC form is the written documented history of any sample and is initiated when bottles are sent to the field, or at the time of sampling. This form is completed by the sampling personnel and accompanies the samples to the laboratory where it is received and stored under the laboratory's custody. The purpose of the COC form is to provide a legal written record of the handling of samples from the time of collection until they are received at the laboratory. It also

serves as the primary written request for analyses from the client to the laboratory. The COC form acts as a purchase order for analytical services when no other contractual agreement is in effect.

23.1.1 Field Documentation

The information the sampler needs to provide at the time of sampling on the container label is:

- Sample identification
- Date and time
- Preservative

During the sampling process, the COC form is completed and must be legible. This form includes information such as:

- Client name, address, phone number and fax number (if available)
- Project name and/or number
- The sample identification
- Date, time and location of sampling
- Sample collectors name
- The matrix description
- The container description
- The total number of each type of container
- Preservatives used
- Analysis requested
- Requested turnaround time (TAT)
- Any special instructions
- Purchase Order number or billing information (e.g. quote number) if available
- The date and time that each person received or relinquished the sample(s), including their signed name.

When the sampling personnel deliver the samples directly to the laboratory personnel, the samples are stored in a cooler with ice, as applicable, and remain solely in the possession of the client's field technician until the samples are delivered to the laboratory personnel. The sample collector must assure that each container is in his/her physical possession or in his/her view at all times, or stored in such a place and manner to preclude tampering. The field technician relinquishes the samples in writing on the COC form to the sample control personnel at the laboratory or to a laboratory courier. When sampling personnel deliver the samples through a common carrier (Fed-Ex, UPS), the CoC relinquished date/time is completed by the field personnel and samples are released to the carrier. Samples are only considered to be received by the laboratory when personnel at the fixed laboratory facility have physical contact with the samples.

Note: Independent couriers are not required to sign the COC form. The COC is usually kept in the sealed sample cooler. The COC is stored with project information and the report.

23.1.2 **Legal / Evidentiary Chain-of-Custody**

If samples are identified for legal/evidentiary purposes on the COC, login will complete the custody seal retain the shipping record with the COC, and initiate an internal COC for laboratory use by analysts and a sample disposal record.

23.2 Sample Receipt

Samples are received at the laboratory by designated sample receiving personnel and a unique laboratory project identification number is assigned. Each sample container shall be assigned a unique sample identification number that is cross-referenced to the client identification number such that traceability of test samples is unambiguous and documented. Each sample container is affixed with a durable sample identification label. Sample acceptance, receipt, tracking and storage procedures are detailed in SOP NC-SC-005, Sample Receiving, and summarized in the following sections.

23.2.1 **Laboratory Receipt**

23.2.1.1 When samples arrive at the laboratory, sample receiving personnel inspect the coolers and samples. The integrity of each sample must be determined by comparing sample labels or tags with the COC and by visual checks of the container for possible damage. Any non-conformance, irregularity, or compromised sample receipt must be documented on a Cooler Receipt Form (CRF) and brought to the immediate attention of the client. The COC, shipping documents, documentation of any non-conformance, irregularity, or compromised sample receipt, record of client contact, and resulting instructions become part of the project record.

Sample Receiving personnel check and document preservation of non-volatile liquid samples in LIMS and before they are released to the laboratory for testing or placed into storage. Any checks of volatile samples and samples for oil and grease are performed and documented at the time of analysis.

23.3 Sample Acceptance Policy

The laboratory has a written sample acceptance policy outlined in SOP NC-SC-005 Sample Receiving that clearly outlines the circumstances under which samples shall be accepted or rejected. These include:

- a COC filled out completely;
- samples must be properly labeled;
- proper sample containers with adequate volume for the analysis (Sampling Guide) and necessary QC;
- samples must be preserved according to the requirements of the requested analytical method (Sampling Guide);
- sample holding times must be adhered to (Sampling Guide);
- All samples submitted for water/solid Volatile Organic analyses must have a Trip Blank submitted at the same time
- the project manager will be notified if any sample is received in damaged condition.

Data from samples which do not meet these criteria are flagged and the nature of the variation from policy is defined.

23.3.1 After inspecting the samples, the sample receiving personnel sign and date the COC form, make any necessary notes of the samples' conditions and store them in appropriate refrigerators or storage locations.

23.3.2 Any deviations from these checks that question the suitability of the sample for analysis, or incomplete documentation as to the tests required will be resolved by consultation with the client. If the sample acceptance policy criteria are not met, the laboratory shall either:

- Retain all correspondence and/or records of communications with the client regarding the disposition of rejected samples, or
- Fully document any decision to proceed with sample analysis that does not meet sample acceptance criteria.

Once sample acceptance is verified, the samples are logged into the LIMS according SOP NC-SC-005.

23.4 Sample Storage

In order to avoid deterioration, contamination or damage to a sample during storage and handling, from the time of receipt until all analyses are complete, samples are stored in refrigerators, freezers or protected locations suitable for the sample matrix. Metals samples may be unrefrigerated. In addition, samples to be analyzed for volatile organic parameters are stored in separate refrigerators designated for volatile organic parameters only. Samples are never to be stored with reagents, standards or materials that may create contamination.

To ensure the integrity of the samples during storage, refrigerator blanks are maintained in the volatile sample refrigerators and analyzed every two weeks.

Analysts and technicians retrieve the sample container allocated to their analysis from the designated refrigerator and place them on carts, analyze the sample, and return the remaining sample or empty container to the refrigerator from which it originally came. All unused portions of samples, including empty sample containers, are returned to the secure sample control area. All samples are kept in cold storage for 30 days after report generation, which meets or exceeds most sample holding times. After this time period, the samples are removed from the refrigerator shelves and prepared for disposal. Special arrangements may be made to store samples for longer periods of time.

Access to the laboratory is controlled such that sample storage need not be locked at all times unless a project specifically demands it. Samples are accessible to laboratory personnel only. Visitors to the laboratory are prohibited from entering the refrigerator and laboratory areas unless accompanied by an employee of Eurofins TestAmerica.

23.5 Hazardous Samples and Foreign Soils

To minimize exposure to personnel and to avoid potential accidents, hazardous and foreign soil samples are stored in an isolated area designated for hazardous waste only. For any sample

that is known to be hazardous at the time of receipt or, if after completion of analysis the result exceeds the acceptable regulatory levels, a Hazardous Sample Notice must be completed by the analyst. This form may be completed by Sample Control, Project Managers, or analysts and must be attached to the report. The sample itself is clearly marked with a red stamp, stamped on the sample label reading "HAZARDOUS" or "FOREIGN SOIL" and placed in a colored and/or marked bag to easily identify the sample. The date, log number, lab sample number, and the result or brief description of the hazard are all written on the Hazardous & Foreign Soil Sample Notice. A copy of the form must be included with the original COC and Work Order and the original must be given to the Sample Control Custodian. Analysts will notify Sample Control of any sample determined to be hazardous after completion of analysis by completing a Hazardous Sample Notice. All hazardous samples are either returned to the client or disposed of appropriately through a hazardous waste disposal firm that lab-packs all hazardous samples and removes them from the laboratory. Foreign soil samples are sent out for incineration by a USDA-approved waste disposal facility.

See SOP NC-SC-019 Procedure of Acceptance and Handling of USDA Regulated Domestic and Foreign Soil for further information.

23.6 Sample Shipping

In the event that the laboratory needs to ship samples, the samples are placed in a cooler with enough ice to ensure the samples remain just above freezing and at or below 6.0°C during transit. The samples are carefully surrounded by packing material to avoid breakage (yet maintain appropriate temperature). A trip blank is enclosed for those samples requiring water/solid volatile organic analyses (see Note). The chain-of-custody form is signed by the sample control technician and attached to the shipping paperwork. Samples are generally shipped overnight express or hand-delivered by a Eurofins TestAmerica courier to maintain sample integrity. All personnel involved with shipping and receiving samples must be trained to maintain the proper chain-of-custody documentation and to keep the samples intact and on ice. The Environmental, Health and Safety Manual contains additional shipping requirements.

Note: If a client does not request trip blank analysis on the COC or other paperwork, the laboratory will not analyze the trip blanks that were supplied. However, in the interest of good client service, the laboratory will advise the client at the time of sample receipt that it was noted that they did not request analysis of the trip blank; and that the laboratory is providing the notification to verify that they are not inadvertently omitting a key part of regulatory compliance testing.

23.7 Sample Disposal

Samples should be retained for a minimum of 30 days after the project report is sent, however, provisions may be made for earlier disposal of samples once the holding time is exceeded. Some samples are required to be held for longer periods based on regulatory or client requirements (e.g., 60 days after project report is sent). The laboratory must follow the longer sample retention requirements where required by regulation or client agreement. Several possibilities for sample disposal exist: the sample may be consumed completely during analysis, the sample may be returned to the customer or location of sampling for disposal, or the sample may be disposed of in accordance with the laboratory's waste disposal procedures (SOP NC-SC-005, Sample Receiving). All procedures in the laboratory's Environmental Health and Safety Manual are followed during disposal. Samples are normally maintained in the laboratory

no longer than two months from receipt unless otherwise requested. Unused portions of samples found or suspected to be hazardous according to state or federal guidelines may be returned to the client upon completion of the analytical work.

If a sample is part of a known litigation, the affected legal authority, sample data user, and/or submitter of the sample must participate in the decision about the sample's disposal. All documentation and correspondence concerning the disposal decision process must be kept on file. Pertinent information includes the date of disposal, nature of disposal (such as sample depletion, hazardous waste facility disposal, return to client), names of individuals who conducted the arrangements and physically completed the task. The laboratory will remove or deface sample labels prior to disposal unless this is accomplished through the disposal method (e.g., samples are incinerated). A Waste Disposal Record should be completed.

All incoming work will be evaluated against the criteria listed below. Where applicable, data from any samples that do not meet the criteria listed below will be noted on the laboratory report defining the nature and substance of the variation. In addition the client will be notified either by telephone, fax or e-mail ASAP after the receipt of the samples.

Per State and/or Federal Regulation, the client is responsible to ensure that samples are shipped in accordance with DOT/IATA requirements, and that radioactive materials may only be delivered to licensed facilities. Any samples containing (or suspected to contain) Source, Byproduct, or Special Nuclear Material as defined by 10 CFR should be delivered directly to facilities licensed to handle such radioactive material. Natural material or ores containing naturally occurring radionuclides may be delivered to any Eurofins TestAmerica facility or courier as long as the activity concentration of the material does not exceed 270 pCi/g alpha or 2700 pCi/g beta (49 CFR Part 173).

1) Samples must arrive with labels intact with a Chain of Custody filled out completely. The following information must be recorded.
   - *Client name, address, phone number and fax number (if available)*
   - *Project name and/or number*
   - *The sample identification*
   - *Date, time and location of sampling*
   - *The collectors name*
   - *The matrix description*
   - *The container description*
   - *The total number of each type of container*
   - *Preservatives used*
   - *Analysis requested*
   - *Requested turnaround time (TAT)*
   - *Any special instructions*
   - *Purchase Order number or billing information (e.g. quote number) if available*
   - *The date and time that each person received or relinquished the sample(s), including their signed name.*
   - *The date and time of receipt must be recorded between the last person to relinquish the samples and the person who receives the samples in the lab, and they must be exactly the same.*
   - Information must be legible

2) Samples must be properly labeled.

- Use durable labels (labels provided by Eurofins TestAmerica are preferred)
- Include a unique identification number
- Include sampling date and time & sampler ID
- Include preservative used.
- Use indelible ink
- Information must be legible

3) Proper sample containers with adequate volume for the analysis and necessary QC are required for each analysis requested. See Lab Sampling Guide.

4) Samples must be preserved according to the requirements of the requested analytical method (See Sampling Guide**.**

5) Most analytical methods require chilling samples to 4° C (other than water samples for metals analysis). For these methods, the criteria are met if the samples are chilled to below 6° C and above freezing (0°C). For methods with other temperature criteria (e.g. some bacteriological methods require ≤ 10 °C), the samples must arrive within ± 2° C of the required temperature or within the method specified range.

   - Samples that are delivered to the laboratory on the same day they are collected may not meet the requirements of Section 5. In these cases, the samples shall be considered acceptable if the samples were received on ice.
   - If sample analysis is begun within fifteen (15) minutes of collection, thermal preservation is not required.
   - Thermal preservation is not required in the field if the laboratory receives and refrigerates the sample within fifteen (15) minutes of collection.
   - Chemical preservation (pH) will be verified prior to analysis and documented, either in sample control or at the analyst's level. The project manager will be notified immediately if there is a discrepancy. If analyses will still be performed, all affected results will be flagged to indicate improper preservation.

Sample Holding Times

- Eurofins TestAmerica Canton will make every effort to analyze samples within the regulatory holding time. Samples must be received in the laboratory with enough time to perform the sample analysis. Except for short holding time samples (< 48hr HT) sample must be received with at least 48 hrs (2 working days) remaining on the holding time for us to ensure analysis.
- Analyses that are designated as "field" analyses (pH, Dissolved Oxygen, Disinfectant Residual; a.k.a. Residual Chlorine,) should be analyzed ASAP by the field sampler prior to delivering to the lab (within 15 minutes). However, if the analyses are to be performed in the laboratory, Eurofins TestAmerica Canton will make every effort to analyze the samples within 24 hours from receipt of the samples in the testing laboratory. Samples for "field" analyses received after 4:00 pm on Friday or on the weekend will be analyzed no later than the next business day after receipt (Monday unless a holiday). Samples will remain refrigerated and sealed until the time of analysis. The actual times of all "field" sample analyses are noted in the final report. Samples analyzed in the laboratory will be qualified on the final report with an 'H' to indicate holding time exceedance.

6) All samples submitted for Volatile Organic analyses should have a Trip Blank submitted at the same time. Eurofins TestAmerica Canton will supply a blank with the bottle order.

7) The project manager will be notified if any sample is received in damaged condition.

8) Recommendations for packing samples for shipment.

   - Pack samples in Ice rather than "Blue" ice packs.
   - Soil samples should be placed in plastic zip-lock bags. The containers often have dirt around the top and do not seal very well and are prone to intrusion from the water from melted ice.

- Water samples would be best if wrapped with bubble-wrap or paper (newspaper, or paper towels work) and then placed in plastic zip-lock bags.
- Fill extra cooler space with bubble wrap.

24 ASSURING THE QUALITY OF TEST RESULTS

24.1 Overview

In order to assure our clients of the validity of their data, the laboratory continuously evaluates the quality of the analytical process. The analytical process is controlled not only by instrument calibration as discussed in Section 20, but also by routine process quality control measurements (e.g. Blanks, Laboratory Control Samples (LCS), Matrix Spikes (MS), duplicates (DUP), surrogates, Internal Standards (IS)). These quality control checks are performed as required by the method or regulations to assess precision and accuracy. Quality control samples are to be treated in the exact same manner as the associated field samples being tested. In addition to the routine process quality control samples, Proficiency Testing (PT) Samples (concentrations unknown to laboratory) are analyzed to help ensure laboratory performance.

24.2 Controls

Sample preparation or pre-treatment is commonly required before analysis. Typical preparation steps include homogenization, grinding, solvent extraction, sonication, acid digestion, distillation, reflux, evaporation, drying and ashing. During these pre-treatment steps, samples are arranged into discreet manageable groups referred to as preparation (prep) batches. Prep batches provide a means to control variability in sample treatment. Control samples are added to each prep batch to monitor method performance and are processed through the entire analytical procedure with investigative/field samples.

24.3 Negative Controls

Table 24-1. Example – Negative Controls

Control Type	Details
Method Blank (MB)	are used to assess preparation and analysis for possible contamination during the preparation and processing steps.
	The specific frequency of use for method blanks during the analytical sequence is defined in the specific standard operating procedure for each analysis. Generally it is 1 for each batch of samples; not to exceed 20 environmental samples.
	The method blank is prepared from a clean matrix similar to that of the associated samples that is free from target analytes (e.g., Reagent water, Ottawa sand, glass beads, etc.) and is processed along with and under the same conditions as the associated samples. The method blank goes through all of the steps of the process (including as necessary: filtration, clean-ups, etc.).
	Reanalyze or qualify associated sample results when the concentration of a targeted analyte in the blank is at or above the reporting limit as established by the method or by regulation, AND is greater than 1/10 of the amount measured in the sample.
Calibration Blanks	are prepared and analyzed along with calibration standards where applicable. They are prepared using the same reagents that are used to prepare the standards. In some analyses the calibration blank may be included in the calibration curve.

Table 24-1. Example – Negative Controls

Control Type	Details
Instrument Blanks	are blank reagents or reagent water that may be processed during an analytical sequence in order to assess contamination in the analytical system. In general, instrument blanks are used to differentiate between contamination caused by the analytical system and that caused by the sample handling or sample prep process. Instrument blanks may also be inserted throughout the analytical sequence to minimize the effect of carryover from samples with high analyte content.
Trip Blank [1]	are required to be submitted by the client with each shipment of samples requiring aqueous and solid volatiles analyses (or as specified in the client's project plan). Additionally, trip blanks may be prepared and analyzed for volatile analysis of air samples, when required by the client. A trip blank may be purchased (certified clean) or is prepared by the laboratory by filling a clean container with pure deionized water that has been purged to remove any volatile compounds. Appropriate preservatives are also added to the container. The trip blank is sent with the bottle order and is intended to reflect the environment that the containers are subjected to throughout shipping and handling and help identify possible sources if contamination is found. The field sampler returns the trip blank in the cooler with the field samples.
Field Blanks [1]	are sometimes used for specific projects by the field samplers. A field blank prepared in the field by filling a clean container with pure reagent water and appropriate preservative, if any, for the specific sampling activity being undertaken. (EPA OSWER)
Equipment Blanks [1]	are also sometimes created in the field for specific projects. An equipment blank is a sample of analyte-free media which has been used to rinse common sampling equipment to check effectiveness of decontamination procedures. (TNI)
Holding Blanks	also referred to as refrigerator or freezer blanks, are used to monitor the sample storage units for volatile organic compounds during the storage of VOA samples in the laboratory

[1] When known, these field QC samples should not be selected for matrix QC as it does not provide information on the behavior of the target compounds in the field samples. Usually, the client sample ID will provide information to identify the field blanks with labels such as "FB", "EB", or "TB."

Evaluation criteria and corrective action for these controls are defined in the specific standard operating procedure for each analysis.

24.4 Positive Controls

Control samples (e.g., QC indicators) are analyzed with each batch of samples to evaluate data based upon (1) Method Performance (Laboratory Control Sample (LCS) or Blank Spike (BS)), which entails both the preparation and measurement steps; and (2) Matrix Effects (Matrix Spike (MS) or Sample Duplicate (MD, DUP), which evaluates field sampling accuracy, precision, representativeness, interferences, and the effect of the matrix on the method performed. Each regulatory program and each method within those programs specify the control samples that are prepared and/or analyzed with a specific batch

Note that frequency of control samples vary with specific regulatory, methodology and project specific criteria. Complete details on method control samples are as listed in each analytical SOP.

24.4.1 Method Performance Control - Laboratory Control Sample (LCS)

The LCS measures the accuracy of the method in a blank matrix and assesses method performance independent of potential field sample matrix affects in a laboratory batch.

The LCS is prepared from a clean matrix similar to that of the associated samples that is free from target analytes (for example: Reagent water, Ottawa sand, glass beads, etc.) and is

processed along with and under the same conditions as the associated samples. The LCS is spiked with verified known amounts of analytes or is made of a material containing known and verified amounts of analytes, taken through all preparation and analysis steps along with the field samples. Where there is no preparation taken for an analysis (such as in aqueous volatiles), or when all samples and standards undergo the same preparation and analysis process, a calibration verification standard is reported as the LCS. In some instances where there is no practical clean solid matrix available, aqueous LCS's may be processed for solid matrices; final results may be calculated as mg/kg or ug/kg, assuming 100% solids and a weight equivalent to the aliquot used for the corresponding field samples, to facilitate comparison with the field samples.

Certified pre-made reference material purchased from a NIST/A2LA accredited vendor may also be used for the LCS when the material represents the sample matrix or the analyte is not easily spiked (e.g. solid matrix LCS for metals, TDS, etc.).

The specific frequency of use for LCS during the analytical sequence is defined in the specific standard operating procedure for each analysis. It is generally 1 for each batch of samples; not to exceed 20 environmental samples.

If the mandated or requested test method, or project requirements, do not specify the spiking components, the laboratory shall spike all reportable components to be reported in the Laboratory Control Sample (and Matrix Spike) where applicable (e.g. no spike of pH). However, in cases where the components interfere with accurate assessment (such as simultaneously spiking chlordane, Toxaphene and PCBs in Method 608), the test method has an extremely long list of components or components are incompatible, at a minimum, a representative number of the listed components (see below) shall be used to control the test method. The selected components of each spiking mix shall represent all chemistries, elution patterns and masses, permit specified analytes and other client requested components. However, the laboratory shall ensure that all reported components are used in the spike mixture within a two-year time period.

- For methods that have 1-10 target analytes, spike all components.
- For methods that include 11-20 target analytes, spike at least 10 or 80%, whichever is greater
- For methods with more than 20 target analytes, spike at least 16 components.
- Exception: Due to analyte incompatibility in pesticides, Toxaphene and Chlordane are only spiked at client request based on specific project needs.
- Exception: Due to analyte incompatibility between the various PCB aroclors, aroclors 1016 and 1260 are used for spiking as they cover the range of all of the aroclors. Specific aroclors may be used by request on a project specific basis.

24.5 Sample Matrix Controls

Table 24-3. Sample Matrix Control

Control Type	Details	
Matrix Spikes (MS)	Use	Used to assess the effect sample matrix of the spiked sample has on the precision and accuracy of the results generated by the method used;
	Typical Frequency [1]	At a minimum, with each matrix-specific batch of samples processed, an MS is carried through the complete analytical procedure. Unless specified by the client, samples used for spiking are randomly selected and rotated between different client projects. If the mandated or requested test method does not specify the spiking components, the laboratory shall spike all reportable components to be reported in the Laboratory Control Sample and Matrix Spike. Refer to the method SOP for complete details
	Description	Essentially a sample fortified with a known amount of the test analyte(s).
Surrogate	Use	Measures method performance to sample matrix (organics only).
	Typical Frequency [1]	Are added to all samples, standards, and blanks, for all organic chromatography methods except when the matrix precludes its use or when a surrogate is not available. The recovery of the surrogates is compared to the acceptance limits for the specific method. Poor surrogate recovery may indicate a problem with sample composition and shall be reported, with data qualifiers, to the client whose sample produced poor recovery.
	Description	Are similar to matrix spikes except the analytes are compounds with properties that mimic the analyte of interest and are unlikely to be found in environment samples.
Duplicates[2]	Use	For a measure of analytical precision, with each matrix-specific batch of samples processed, a matrix duplicate (MD or DUP) sample, matrix spike duplicate (MSD), or LCS duplicate (LCSD) is carried through the complete analytical procedure.
	Typical Frequency [1]	Duplicate samples are usually analyzed with methods that do not require matrix spike analysis.
	Description	Performed by analyzing two aliquots of the same field sample independently or an additional LCS.
Internal Standards	Use	Are spiked into all environmental and quality control samples (including the initial calibration standards) to monitor the qualitative aspect of organic and some inorganic analytical measurements.
	Typical Frequency [1]	All organic and ICP methods as required by the analytical method.
	Description	Used to correct for matrix effects and to help troubleshoot variability in analytical response and are assessed after data acquisition. Possible sources of poor internal standard response are sample matrix, poor analytical technique or instrument performance.

[1] See the specific analytical SOP for type and frequency of sample matrix control samples.
[2] LCSD's are normally not performed except when regulatory agencies or client specifications require them. The recoveries for the spiked duplicate samples must meet the same laboratory established recovery limits as the accuracy QC samples. If an LCSD is analyzed both the LCS and LCSD must meet the same recovery criteria and be included in the final report. The precision measurement is reported as "Relative Percent Difference" (RPD). Poor precision between duplicates (except LCS/LCSD) may indicate non-homogeneous matrix or sampling.

24.6 Acceptance Criteria (Control Limits)

As mandated by the test method and regulation, each individual analyte in the LCS, MS, or Surrogate Spike is evaluated against the control limits published in the test method. Where there are no established acceptance criteria, the laboratory calculates in-house control limits with the use of control charts or, in some cases, utilizes client project specific control limits. When this occurs, the regulatory or project limits will supersede the laboratory's in-house limits.

Note: For methods, analytes and matrices with very limited data (e.g., unusual matrices not analyzed often), interim limits are established using available data or by analogy to similar methods or matrices.

Note: For Ohio VAP the laboratory must implement Corrective Action procedures to resolve the deviation and limit qualification of the final results. The laboratory is not permitted to deviate from its VAP approved SOP if it intends to attest under affidavit that the "results" are VAP certified. When all corrective actions listed in the SOP have been exhausted, it may be necessary to use technical judgment in which case the decision process and rationale will be presented in the final report and/or affidavit and the data will be noted as 'not VAP certified' on the affidavit.

Once control limits have been established, they are verified, reviewed, and updated if necessary on an annual basis unless the method requires more frequent updating. Control limits are established per method (as opposed to per instrument) regardless of the number of instruments utilized.

Laboratory generated % Recovery acceptance (control) limits are generally established by taking $\pm$ 3 Standard Deviations (99% confidence level) from the average recovery of a minimum of 20-30 data points (more points are preferred).

- Regardless of the calculated limit, the limit should be no tighter than the Calibration Verification (ICV/CCV) (unless the analytical method specifies a tighter limit).

- In-house limits cannot be any wider than those mandated in a regulated analytical method. Client or contract required control limits are evaluated against the laboratory's statistically derived control limits to determine if the data quality objectives (DQOs) can be achieved. If laboratory control limits are not consistent with DQOs, then alternatives must be considered, such as method improvements or use of an alternate analytical method.

- The lowest acceptable recovery limit will be 10% (the analyte must be detectable and identifiable). Exception: The lowest acceptable recovery limit for Benzidine will be 5% and the analyte must be detectable and identifiable.

- The maximum acceptable recovery limit will be 200%.

- The maximum acceptable RPD limit will be 35% for waters and 40% for soils. The minimum RPD limit is 10%.

- If either the high or low end of the control limit changes by $\leq$ 5% from previous, the control chart is visually inspected and, using professional judgment, they may be left unchanged if there is no effect on laboratory ability to meet the existing limits.

24.6.1 The lab must be able to generate a current listing of their control limits and track when the updates are performed. In addition, the laboratory must be able to recreate historical control limits. Refer to NC-QA-018, Statistical Evaluation of Data and Development of Control Charts for details.

24.6.2 A LCS that is within the acceptance criteria establishes that the analytical system is in control and is used to validate the process. Samples that are analyzed with an LCS with recoveries outside of the acceptance limits may be determined as out of control and should be reanalyzed if possible. If reanalysis is not possible, then the results for all affected analytes for samples within the same batch must be qualified when reported. The internal corrective action process (see Section 12) is also initiated if an LCS exceeds the acceptance limits. Sample results may be qualified and reported without reanalysis if:

- The analyte results are below the reporting limit and the LCS is above the upper control limit.
- If the analytical results are above the relevant regulatory limit and the LCS is below the lower control limit.

Or, for TNI work, there are an allowable number of Marginal Exceedances (ME):

<11 analytes	0 marginal exceedances are allowed.
11 – 30 Analytes	1 marginal exceedance is allowed
31-50 Analytes	2 marginal exceedances are allowed
51-70 Analytes	3 marginal exceedances are allowed
71-90 Analytes	4 marginal exceedances are allowed
> 90 Analytes	5 marginal exceedances are allowed

- Marginal exceedances are recovery exceedances between 3 SD and 4 SD from the mean recovery limit (TNI).
- Marginal exceedances must be random. If the same analyte exceeds the LCS control limit repeatedly, it is an indication of a systematic problem. The source of the error must be located and corrective action taken. The laboratory has a system to monitor marginal exceedances to ensure that they are random.

Note: Ohio VAP does not allow the use of marginal exceedance.

Though marginal exceedances may be allowed by other programs, the data must still be qualified to indicate it is outside of the normal limits.

24.6.3 If the MS/MSDs do not meet acceptance limits, the MS/MSD and the associated spiked sample is reported with a qualifier for those analytes that do not meet limits. If obvious preparation errors are suspected, or if requested by the client, unacceptable MS/MSDs are reprocessed and reanalyzed to prove matrix interference. A more detailed discussion of acceptance criteria and corrective action can be found in the lab's method SOPs and in Section 12.

24.6.4 If a surrogate standard falls outside the acceptance limits, and if there is not obvious chromatographic matrix interference, reanalyze the sample to confirm a possible matrix effect. If the recoveries confirm or there was obvious chromatographic interference, results are reported from the original analysis and a qualifier is added. If the reanalysis meets surrogate recovery criteria, the second run is reported (or both are reported if

requested by the client). Under certain circumstances, where all of the samples are from the same location and share similar chromatography, the reanalysis may be performed on a single sample rather than all of the samples and if the surrogate meets the recovery criteria in the reanalysis, all of the affected samples would require reanalysis.

24.7 Additional Procedures to Assure Quality Control

The laboratory has written and approved method SOPs to assure the accuracy of the test method including calibration (see Section 20), use of certified reference materials (see Section 21) and use of PT samples (see Section 17).

A discussion regarding MDLs, Limit of Detection (LOD) and Limit of Quantitation (LOQ) can be found in Section 19.

- Use of formulae to reduce data is discussed in the method SOPs and in Section 20.
- Selection of appropriate reagents and standards is included in Section 11 and 21.
- A discussion on selectivity of the test is included in Section 7.
- Constant and consistent test conditions are discussed in Section 6.
- The laboratories sample acceptance policy is included in Section 23.

25 REPORTING RESULTS

25.1 Overview

The results of each test are reported accurately, clearly, unambiguously, and objectively in accordance with State and Federal regulations as well as client requirements. Analytical results are issued in a format that is intended to satisfy customer and laboratory accreditation requirements as well as provide the end user with the information needed to properly evaluate the results. Where there is conflict between client requests and laboratory ethics or regulatory requirements, the laboratory's ethical and legal requirements are paramount, and the laboratory will work with the client during project set up to develop an acceptable solution. Refer to Section 9.

A variety of report formats are available to meet specific needs.

In cases where a client asks for simplified reports, there must be a written request from the client. There still must be enough information that would show any analyses that were out of conformance (QC out of limits) and there should be a reference to a full report that is made available to the client. Review of reported data is included in Section 19.

25.2 Test Reports

Analytical results are reported in a format that is satisfactory to the client and meets all requirements of applicable accrediting authorities and agencies. A variety of report formats are available to meet specific needs. The report is printed on laboratory letterhead, reviewed, and signed by the appropriate project manager. At a minimum, the standard laboratory report shall contain the following information:

25.2.1 A report title (e.g., Analytical Report)

25.2.2 The cover page shall include the laboratory name, address and telephone number.

25.2.3 A unique identification of the report (e.g., Eurofins TestAmerica Canton Job ID #) and on each page an identification in order to ensure the page is recognized as part of the report and a clear identification of the end.

Note: Page numbers of report are represented as page # of ##. Where the first number is the page number and the second is the total number of pages.

25.2.4. A copy of the chain of custody (COC)

- Any COCs involved with Subcontracting are included.

25.2.5. The name and address of client and a project name/number, if applicable.

25.2.6. Client project manager or other contact

25.2.7. Description and unambiguous identification of the tested sample(s) including the client identification code

25.2.8. Date of receipt of sample, date and time of collection, and date(s) of test preparation and performance, and time of preparation or analysis if the required holding time for either activity is less than or equal to 72 hours.

25.2.9. Date reported or date of revision, if applicable.

25.2.10. Method of analysis including method code (EPA, Standard Methods, etc.)

25.2.11. Practical quantitation limits or reporting limit.

25.2.12. Method detection limits (if requested)

25.2.13. Definition of Data qualifiers and reporting acronyms (e.g. ND)

25.2.14. Sample results

25.2.15. QC data consisting of method blank, surrogate, LCS, and MS/MSD recoveries and control limits

25.2.16. Condition of samples at receipt including temperature. This may be accomplished in a narrative or by attaching sample login sheets (Refer to Sec. 25.2.4 – Item 3 regarding additional addenda).

25.2.17. A statement expressing the validity of the results, that the source methodology was followed and all results were reviewed for error.

25.2.18. A statement to the effect that the results relate only to the items tested and the sample as received by the laboratory, except when information is provided by the

client. When data is provided by the client there shall be a clear identification of it, and a disclaimer shall be put in the report when the client supplied data can affect the validity of the test.

25.2.19. A statement that the report shall not be reproduced except in full, without prior express written approval by the laboratory coordinator.

25.2.20. A signature and title of the person(s) accepting responsibility for the content of the report and date of issue. Authorized signatories are qualified Project Managers appointed by the Manager of Project Managers.

25.2.21. When TNI accreditation is required, the lab shall certify that the test results meet all requirements of TNI or provide reasons and/or justification if they do not.

25.2.22. Where applicable, a narrative to the report that explains the issue(s) and corrective action(s) taken in the event that a specific accreditation or certification requirement was not met.

25.2.23. When soil samples are analyzed, a specific identification as to whether soils are reported on a “wet weight” or “dry weight” basis.

25.2.24. Appropriate laboratory certification number for the state of origin of the sample, if applicable.

25.2.25. If only part of the report is provided to the client (client requests some results before all of it is complete), it must be clearly indicated on the report (e.g., partial report, or how your lab identifies it). A complete report must be sent once all of the work has been completed.

25.2.26. Any non-Eurofins TestAmerica Canton subcontracted analysis results are provided as a separate report on the official letterhead of the subcontractor. All Eurofins TestAmerica Canton subcontracting is clearly identified on the report as to which laboratory performed a specific analysis.

25.2.27. A Certification Summary Report, where required, will document that, unless otherwise noted, all analytes tested and reported by the laboratory were covered by the noted certifications.

Note: Refer to the NDSC Document No. CA-I-P-002 Electronic Reporting and Signature Policy for details on internally applying electronic signatures of approval.

25.2.28. Reports for Ohio VAP work require a VAP affidavit be completed and included with the report.

25.2.29. Where the laboratory is responsible for the sampling stage, in addition to the requirements listed above, reports containing the results of sampling shall include the following, where necessary for the interpretation of test results:

- the date of sampling;

- unambiguous identification of the material sampled;
- the location of sampling plan and procedures, and deviations, addition to or exclusions from the sample procedures;
- a reference to the sampling plan and procedure, and deviations, additions to or exclusions from the sample procedures;
- details of any environmental conditions during sampling that affect the interpretation of test results;
- information required to evaluate measurement uncertainty for subsequent testing

25.3 Reporting Level or Report Type

The laboratory offers four levels of quality control reporting. Each level, in addition to its own specific requirements, contains all the information provided in the preceding level. The packages provide the following information in addition to the information described above:

- Level 1 is a report with all of the elements outlined in Section 25.2 above, excluding 25.2.15 (QC data).
- Level II is a Level I report plus summary information, including results for the method blank reported to the laboratory MDL, percent recovery for laboratory control samples and matrix spike samples, and the RPD values for all MSD and sample duplicate analyses.
- Level III contains all the information supplied in Level II, but presented on the CLP-like summary forms, and relevant calibration information. A Level II report is not included, unless specifically requested. No raw data is provided.
- Level IV is the same as Level III with the addition of all raw supporting data.

In addition to the various levels of QC packaging, the laboratory also provides reports in EDD (see below) Initial reports may be provided to clients by facsimile. Procedures used to ensure client confidentiality are outlined in Section 25.6.

25.4 Electronic Data Deliverables (EDDs)

EDDs are routinely offered as part of Eurofins TestAmerica Canton's services in addition to the test report as described in Section 25.2. When NELAP accreditation is required and both a test report and EDD are provided to the client, the official version of the test report will be the combined information of the report and the EDD. Eurofins TestAmerica Canton offers a variety of EDD formats including Environmental Restoration Information Management System (ERPIMS), Staged Electronic Data Deliverable (SEDD) Environmental Quality Information System (EQuIS), Electronic Deliverable Format (EDF), Excel and custom files.

EDD specifications are submitted to the IT department by the PM for review and undergo the contract review process. Once the facility has committed to providing data in a specific electronic format, the coding of the format may need to be performed. This coding is documented and validated. The validation of the code is retained by the IT staff coding the EDD.

EDDs shall be subject to a review to ensure their accuracy and completeness. If EDD generation is automated, review may be reduced to periodic screening if the laboratory can

demonstrate that it can routinely generate that EDD without errors. Any revisions to the EDD format must be reviewed until it is demonstrated that it can routinely be generated without errors. If the EDD can be reproduced accurately and if all subsequent EDDs can be produced error-free, each EDD does not necessarily require a review.

25.5 Supplemental Information for Test

The lab identifies any unacceptable QC analyses or any other unusual circumstances or observations such as environmental conditions and any non-standard conditions that may have affected the quality of a result. This is typically in the form of a footnote or a qualifier and/or a narrative explaining the discrepancy in the front of the report.

Numeric results with values outside of the calibration range, either high or low are qualified as estimated.

Where quality system requirements are not met, a statement of compliance/non-compliance with requirements and/or specifications is required, including identification of test results derived from any sample that did not meet TNI sample acceptance requirements such as improper container, holding time, or temperature.

Where applicable, a statement on the estimated uncertainty of measurements; information on uncertainty is needed when a client's instructions so require.

When, as requested by the client and agreed to by Eurofins TestAmerica Canton, the report includes a statement of conformity to specification or standard (see Special Services, Section 7.4), the report shall clearly identify:

- to which results the statement applies,
- which specifications, standard or parts thereof are met or not, and
- the decision rule that was applied (unless the decision rule is inherent in the requested specification or standard, taking into account the level of risk (such as false accept and false reject and statistical assumptions) associated with the decision rule.

Opinions and Interpretations - The test report contains objective information, and generally does not contain subjective information such as opinions and interpretations. If such information is required by the client, the Laboratory Director will determine if a response can be prepared. If so, the Laboratory Director will designate the appropriate member of the management team to prepare a response. The response will be fully documented, and reviewed by the Laboratory Director, before release to the client. There may be additional fees charged to the client at this time, as this is a non-routine function of the laboratory.

Note: Review of data deliverable packages for submittal to regulatory authorities requires responses to non-conforming data concerning potential impact on data quality. This necessitates a limited scope of interpretation, and this work is performed by the QA Department. This is the only form of "interpretation" of data that is routinely performed by the laboratory.

When opinions or interpretations are included in the report, the laboratory provides an explanation as to the basis upon which the opinions and interpretations have been made. Opinions and interpretations are clearly noted as such and where applicable, a comment should be added suggesting that the client verify the opinion or interpretation with their regulator.

25.6 Environmental Testing Obtained From Subcontractors

If the laboratory is not able to provide the client the requested analysis, the samples would be subcontracted following the procedures outlined in the NDSC Document No. CW-L-S-004, Subcontracting.

Data reported from analyses performed by a subcontractor laboratory are clearly identified as such on the analytical report provided to the client. Results from a subcontract laboratory outside of Eurofins TestAmerica Canton are reported to the client on the subcontract laboratory's original report stationary and the report includes any accompanying documentation.

25.7 Client Confidentiality

The laboratory will ensure the highest standards of quality and integrity of the data and services provided to our clients

The laboratory is responsible for maintaining in confidence all client information obtained or created. In situations involving the transmission of environmental test results by telephone, facsimile or other electronic means, client confidentiality must be maintained.

The laboratory will not intentionally divulge to any person (other than the client or any other person designated by the client in writing) any information regarding the services provided by the laboratory or any information disclosed to the laboratory by the client. Furthermore, information known to be potentially endangering to national security or an entity's proprietary rights will not be released.

Information about the client obtained from sources other than the client (e.g., complainant, regulators) shall be confidential between client and the laboratory. The source of this information shall be confidential to the laboratory and shall not be shared with the client, unless agreed by the source.

Note: This shall not apply to the extent that the information is required to be disclosed by the laboratory under the compulsion of legal process. The laboratory will, to the extent feasible, provide reasonable notice to the client before disclosing the information.

Note: Authorized representatives of an accrediting authority are permitted to make copies of any analyses or records relevant to the accreditation process, and copies may be removed from the laboratory for purposes of assessment.

25.7.1 Report deliverable formats are discussed with each new client. If a client requests that reports be e-mailed, the reports are to meet all requirements of this document.

25.8 Format of Reports

The format of reports is designed to accommodate each type of environmental test carried out and to minimize the possibility of misunderstanding or misuse.

25.9 Amendments to Test Reports

Corrections, additions, or deletions to reports are only made when justification arises through supplemental documentation. Justification is documented using the laboratory's corrective action system (refer to Section 12).

The revised report is retained on the Archive data server, as is the original report. The revised report is stored in the Archive data server under the sample number followed by "R" The revised report will have the word "revised" or "amended" next to the date rather than the word "reported".

When the report is re-issued, a notation of "report re-issue" is placed on the cover/signature page of the report *or at the top of the narrative page* with a brief explanation of reason for the re-issue and a reference back to the last final report generated.

25.10 Policies on Client Requests for Amendments

25.10.1 Policy on Data Omissions or Reporting Limit Increases

Fundamentally, our policy is simply to not omit previously reported results (including data qualifiers) or to not raise reporting limits and report sample results as ND. This policy has few exceptions. Exceptions are:

- Laboratory error
- Sample identification is indeterminate (confusion between COC and sample labels).
- An incorrect analysis (not analyte) was requested (e.g., COC lists 8315 but client wanted 8310). A written request for the change is required.
- Incorrect limits reported based on regulatory requirements.
- The requested change has absolutely *no possible* impact on the interpretation of the analytical results and there is *no possibility* of the change being interpreted as misrepresentation by anyone inside or outside of our company.

25.10.2 Multiple Reports

The laboratory does not issue multiple reports for the same work order where there is different information on each report (this does not refer to copies of the same report) unless required to meet regulatory needs and approved by QA.

Appendix 1. List of Governing Documents applicable to the QA Manual

(NDSC, KDG and Laboratory SOPs and Policies)

NDSC Doc. No.	Title
CA-I-P-002	Electronic Reporting and Signature Policy

Appendix 2. List of Laboratory Certifications, Accreditations, Validations

The laboratory maintains accreditations, certifications, and approvals with numerous state and national entities. Programs vary but may include on-site audits, reciprocal agreements with another entity, performance testing evaluations, review of the QA Manual, Standard Operating Procedures, Method Detection Limits, training records, etc. At the time of this QA Manual revision, the laboratory has accreditation/ certification/licensing with the following organizations:

Organization	Certificate Number	Organization	Certificate Number
California	2927	Iowa	421
Connecticut	PH-0590	New Jersey	OH001
Florida	E87225	New York	10975
Georgia	---	OVAP	CL0024
Illinois	200004	Pennsylvania	68-00340
Kansas	E-10336	USDA (Dept. of Agriculture)	P330-18-00281
Kentucky Underground Storage Tank Program	112225	Washington	C971
Minnesota	039-999-348	West Virginia	210
Texas	T104704517-20-12 Changes based on the year and month of date of issue	Virginia	460175
Oregon	4062	Kentucky Wastewater	KY98016
Minnesota Petrofund	3506		

Appendix 3. References used to prepare the QA Manual

The QAM has been prepared to be consistent with the requirements of the following documents:

Appendix 5. Terms/Glossary and Acronyms (EL-V1M2 Sec. 3.1)

Acceptance Criteria: Specified limits placed on characteristics of an item, process, or service defined in requirement documents. (ASQC)

Accreditation: The process by which an agency or organization evaluates and recognizes a laboratory as meeting certain predetermined qualifications or standards, thereby accrediting the laboratory.

Accuracy: The degree of agreement between an observed value and an accepted reference value. Accuracy includes a combination of random error (precision) and systematic error (bias) components which are due to sampling and analytical operations; a data quality indicator. (QAMS)

Analyst: The designated individual who performs the "hands-on" analytical methods and associated techniques and who is the one responsible for applying required laboratory practices and other pertinent quality controls to meet the required level of quality.

Analytical Uncertainty: A subset of Measurement Uncertainty that includes all laboratory activities performed as part of the analysis. (TNI)

Anomaly: A condition or event, other than a deficiency, that may affect the quality of the data, whether in the laboratory's control or not.

Assessment: The evaluation process used to measure or establish the performance, effectiveness, and conformance of an organization and/or its systems to defined criteria (to the standards and requirements of laboratory accreditation). (TNI)

Audit: A systematic and independent examination of facilities, equipment, personnel, training, procedures, record-keeping, data validation, data management, and reporting aspects of a system to determine whether QA/QC and technical activities are being conducted as planned and whether these activities will effectively achieve quality objectives. (TNI)

Batch: Environmental samples that are prepared and/or analyzed together with the same process and personnel, using the same lot(s) of reagents. A **preparation batch** is composed of one (1) to twenty (20) environmental samples of the same quality systems matrix, meeting the above mentioned criteria and with a maximum time between the start of processing of the first and last sample in the batch to be twenty-four (24) hours. An **analytical batch** is composed of prepared environmental samples (extracts, digestates or concentrates) which are analyzed together as a group. An analytical batch can include prepared samples originating from various quality system matrices and can exceed twenty (20) samples. (TNI)

Bias: The systematic or persistent distortion of a measurement process, which causes errors in one direction (i.e., the expected sample measurement is different from the sample's true value). (TNI)

Blank: A sample that has not been exposed to the analyzed sample stream in order to monitor contamination during sampling, transport, storage or analysis. The blank is subjected to the usual analytical and measurement process to establish a zero baseline or background value and is sometimes used to adjust or correct routine analytical results. (ASQC)

Calibration: A set of operations that establish, under specified conditions, the relationship between values of quantities indicated by a measuring instrument or measuring system, or values represented by a material measure or a reference material, and the corresponding values realized by standards. (TNI)

1) In calibration of support equipment the values realized by standards are established through the use of reference standards that are traceable to the International System of Units (SI).

2) In calibration according to methods, the values realized by standards are typically established through the use of Reference Materials that are either purchased by the laboratory with a certificate of analysis or purity, or prepared by the laboratory using support equipment that has been calibrated or verified to meet specifications.

Calibration Curve: The mathematical relationship between the known values, such as concentrations, of a series of calibration standards and their instrument response. (TNI)

Calibration Standard: A substance or reference material used to calibrate an instrument (QAMS)

Certified Reference Material (CRM): A reference material accompanied by a certificate, having a value, measurement uncertainty, and stated metrological traceability chain to a national metrology institute. (TNI)

Chain of Custody (COC) Form: Record that documents the possession of the samples from the time of collection to receipt in the laboratory. This record generally includes: the number and types of containers; the mode of collection; the collector; time of collection; preservation; and requested analyses. (TNI)

Compromised Samples: Those samples which are improperly sampled, insufficiently documented (chain of custody and other sample records and/or labels), improperly preserved, collected in improper containers, or exceeding holding times when delivered to a laboratory. Under normal conditions, compromised samples are not analyzed. If emergency situation require analysis, the results must be appropriately qualified.

Confidential Business Information (CBI): Information that an organization designates as having the potential of providing a competitor with inappropriate insight into its management, operation or products. TNI and its representatives agree to safeguard identified CBI and to maintain all information identified as such in full confidentiality.

Confirmation: Verification of the identity of a component through the use of an approach with a different scientific principle from the original method. These may include, but are not limited to Second Column Confirmation; Alternate wavelength; Derivatization; Mass spectral interpretation; Alternative detectors or Additional Cleanup procedures. (TNI)

Conformance: An affirmative indication or judgment that a product or service has met the requirements of the relevant specifications, contract, or regulation; also the state of meeting the requirements. (ANSI/ASQC E4-1994)

Correction: Actions necessary to correct or repair analysis specific non-conformances. The acceptance criteria for method specific QC and protocols as well as the associated corrective actions. The analyst will most frequently be the one to identify the need for this action as a result of calibration checks and QC sample analysis**.** No significant action is taken to change behavior, process or procedure.

Corrective Action: The action taken to eliminate the causes of an existing nonconformity, defect or other undesirable situation in order to prevent recurrence. (ISO 8402)

Data Integrity: The condition that exists when data are sound, correct, and complete, and accurately reflect activities and requirements. (TNI)

Data Audit: A qualitative and quantitative evaluation of the documentation and procedures associated with environmental measurements to verify that the resulting data re of acceptable quality (i.e., that they meet specified acceptance criteria).

Data Reduction: The process of transforming the number of data items by arithmetic or statistical calculations, standard curves, and concentration factors, and collation into a more useable form. (TNI)

Deficiency: An unauthorized deviation from acceptable procedures or practices, or a defect in an item (ASQC), whether in the laboratory's control or not.

Demonstration of Capability: A procedure to establish the ability of the analyst to generate analytical results of acceptable accuracy and precision. (TNI)

Document Control: The act of ensuring that documents (and revisions thereto) are proposed, reviewed for accuracy, approved for release by authorized personnel, distributed properly, and controlled to ensure use of the correct version at the location where the prescribed activity if performed. (ASQC)

Duplicate Analyses: The analyses or measurements of the variable of interest performed identically on two subsamples of the same sample. The results from duplicate analyses are used to evaluate analytical or measurement precision but not the precision of sampling, preservation or storage internal to the laboratory. (EPA-QAD)

Equipment Blank: Sample of analyte-free media which has been used to rinse common sampling equipment to check effectiveness of decontamination procedures.

External Standard Calibration: Calibrations for methods that do not utilize internal standards to compensate for changes in instrument conditions.

Field Blank: Blank prepared in the field by filing a clean container with pure de-ionized water and appropriate preservative, if any, for the specific sampling activity being undertaken (EPA OSWER)

Field of Accreditation: Those matrix, technology/method, and analyte combinations for which the accreditation body offers accreditation.

Holding Times: The maximum time that samples may be held prior to analyses and still be considered valid or not compromised. (40 CFR Part 136)

Internal Standard: A known amount of standard added to a test portion of a sample as a reference for evaluating and controlling the precision and bias of the applied analytical test method. (TNI)

Internal Standard Calibration: Calibrations for methods that utilize internal standards to compensate for changes in instrument conditions.

Instrument Blank: A clean sample (e.g., distilled water) processed through the instrumental steps of the measurement process; used to determine instrument contamination. (EPA-QAD)

Instrument Detection Limit (IDL): The minimum amount of a substance that can be measured with a specified degree of confidence that the amount is greater than zero using a specific instrument. The IDL is associated with the instrumental portion of a specific method only, and sample preparation steps are not considered in its derivation. The IDL is a statistical estimation at a specified confidence interval of the concentration at which the relative uncertainty is ± 100%. The IDL represents a range where qualitative detection occurs on a specific instrument. Quantitative results are not produced in this range.

Laboratory Control Sample (however named, such as laboratory fortified blank, spiked blank, or QC check sample): A sample matrix, free from the analytes of interest, spiked with verified known amounts of analytes or a material containing known and verified amounts of analytes, taken through all preparation and analysis steps of the procedure unless otherwise noted in a reference method. It is

generally used to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.

An LCS shall be prepared at a minimum of 1 per batch of 20 or less samples per matrix type per sample extraction or preparation method except for analytes for which spiking solutions are not available such as total suspended solids, total dissolved solids, total volatile solids, total solids, pH, color, odor, temperature, dissolved oxygen or turbidity. The results of these samples shall be used to determine batch acceptance.

Least Squares Regression (1st Order Curve): The least squares regression is a mathematical calculation of a straight line over two axes. The y axis represents the instrument response (or Response ratio) of a standard or sample and the x axis represents the concentration. The regression calculation will generate a correlation coefficient (r) that is a measure of the "goodness of fit" of the regression line to the data. A value of 1.00 indicates a perfect fit. In order to be used for quantitative purposes, r must be greater than or equal to 0.99 for organics and 0.995 for inorganics.

Limit(s) of Detection (LOD) [a.k.a., Method Detection Limit (MDL)]: The MDL is the minimum measured quantity of a substance that can be reported with 99% confidence that the concentration is distinguishable from method blank results, consistent with 40CFR Part 136 Appendix B, August, 2017.

Limit(s) of Quantitation (LOQ) [a.k.a., Reporting Limit]: The minimum levels, concentrations, or quantities of a target variable (e.g., target analyte) that can be reported with a specified degree of confidence.

(QS) Matrix: The component or substrate that contains the analyte of interest. For purposes of batch and QC requirement determinations, the following matrix distinctions shall be used:

Aqueous: Any aqueous sample excluded from the definition of Drinking Water or Saline/Estuarine. Includes surface water, groundwater effluents, and TCLP or other extracts.

Drinking Water: Any aqueous sample that has been designated as a potable or potential potable water source.

Saline/Estuarine: Any aqueous sample from an ocean or estuary, or other salt water source such as the Great Salt Lake.

Non-Aqueous Liquid: Any organic liquid with <15% settleable solids.

Biological Tissue: Any sample of a biological origin such as fish tissue, shellfish, or plant material. Such samples shall be grouped according to origin.

Solids: Includes soils, sediments, sludges, and other matrices with >15% settleable solids.

Chemical Waste: A product or by-product of an industrial process that results in a matrix not previously defined.

Air & Emissions: Whole gas or vapor samples including those contained in flexible or rigid wall containers and the extracted concentrated analytes of interest from a gas or vapor that are collected with a sorbant tube, impinger solution, filter, or other device. (TNI)

Matrix Spike (spiked sample or fortified sample): A sample prepared, taken through all sample preparation and analytical steps of the procedure unless otherwise noted in a referenced method, by adding a known amount of target analyte to a specified amount of sample for which an independent test

result of target analyte concentration is available. Matrix spikes are used, for example, to determine the effect of the matrix on a method's recovery efficiency.

Matrix Spike Duplicate (spiked sample or fortified sample duplicate): A replicate matrix spike prepared and analyzed to obtain a measure of the precision of the recovery for each analyte.

Method Blank: A sample of a matrix similar to the batch of associated samples (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences are present at concentrations that impact the analytical results for sample analyses.

Method Detection Limit: See Limit of Detection (LOD)

Negative Control: Measures taken to ensure that a test, its components, or the environment do not cause undesired effects, or produce incorrect test results.

Non-conformance: An indication, judgment, or state of not having met the requirements of the relevant specifications, contract, or regulation.

Observation: A record of phenomena that (1) may assist in evaluation of the sample data; (2) may be of importance to the project manager and/or the client, and yet not at the time of the observation have any known effect on quality.

Performance Audit: The routine comparison of independently obtained qualitative and quantitative measurement system data with routinely obtained data in order to evaluate the proficiency of an analyst or laboratory.

Positive Control: Measures taken to ensure that a test and/or its components are working properly and producing correct or expected results from positive test subjects.

Precision: The degree to which a set of observations or measurements of the same property, obtained under similar conditions, conform to themselves; a data quality indicator. Precision is usually expressed as standard deviation, variance or range, in either absolute or relative terms. (TNI)

Preservation: Any conditions under which a sample must be kept in order to maintain chemical and/or biological integrity prior to analysis. (TNI)

Proficiency Testing: A means of evaluating a laboratory's performance under controlled conditions relative to a given set of criteria through analysis of unknown samples provided by an external source. (TNI)

Proficiency Testing Program: The aggregate of providing rigorously controlled and standardized environmental samples to a laboratory for analysis, reporting of results, statistical evaluation of the results and the collective demographics and results summary of all participating laboratories. (TNI)

Proficiency Test Sample (PT): A sample, the composition of which is unknown to the laboratory and is provided to test whether the laboratory can produce analytical results within specified acceptance criteria. (TNI)

Quality Assurance: An integrated system of management activities involving planning, implementation, assessment, reporting and quality improvement to ensure that a process, item or service is of the type of quality needed and expected by the client. (TNI)

Quality Assurance [Project] Plan (QAPP): A formal document describing the detailed quality control procedures by which the quality requirements defined for the data and decisions pertaining to a specific project are to be achieved. (EAP-QAD)

Quality Control: The overall system of technical activities that measures the attributes and performance of a process, item, or service against defined standards to verify that they meet the stated requirements established by the customer; operational techniques and activities that are used to fulfill requirements for quality; also the system of activities and checks used to ensure that measurement systems are maintained within prescribed limits, providing protection against "out of control" conditions and ensuring that the results are of acceptable quality. (TNI)

Quality Control Sample: A sample used to assess the performance of all or a portion of the measurement system. One of any number of samples, such as Certified Reference Materials, a quality system matrix fortified by spiking, or actual samples fortified by spiking, intended to demonstrate that a measurement system or activity is in control. (TNI)

Quality Manual: A document stating the management policies, objectives, principles, organizational structure and authority, responsibilities, accountability, and implementation of an agency, organization, or laboratory, to ensure the quality of its product and the utility of its product to its users. (TNI)

Quality System: A structured and documented management system describing the policies, objectives, principles, organizational authority, responsibilities, accountability, and implementation plan of an organization for ensuring quality in its work processes, products (items), and services. The quality system provides the framework for planning, implementing, and assessing work performed by the organization and for carrying out required QA and QC activities. (TNI)

Raw Data: The documentation generated during sampling and analysis. This documentation includes, but is not limited to, field notes, electronic data, magnetic tapes, untabulated sample results, QC sample results, print outs of chromatograms, instrument outputs, and handwritten records. (TNI)

Record Retention: The systematic collection, indexing and storing of documented information under secure conditions.

Reference Material: Material or substance one or more properties of which are sufficiently homogeneous and well established to be used for the calibration of an apparatus, the assessment of a measurement method, or for assigning values to materials. (TNI)

Reference Standard: Standard used for the calibration of working measurement standards in a given organization or a given location. (TNI)

Sampling: Activity related to obtaining a representative sample of the object of conformity assessment, according to a procedure.

Second Order Polynomial Curve (Quadratic): The 2nd order curves are a mathematical calculation of a slightly curved line over two axis. The y axis represents the instrument response (or Response ratio) of a standard or sample and the x axis represents the concentration. The 2nd order regression will generate a coefficient of determination (COD or r^2) that is a measure of the "goodness of fit" of the quadratic curvature the data. A value of 1.00 indicates a perfect fit. In order to be used for quantitative purposes, r^2 must be greater than or equal to 0.99.

Selectivity: The ability to analyze, distinguish, and determine a specific analyte or parameter from another component that may be a potential interferent or that may behave similarly to the target analyte or parameter within the measurement system. (TNI)

Sensitivity: The capability of a method or instrument to discriminate between measurement responses representing different levels (e.g., concentrations) of a variable of interest. (TNI)

Spike: A known mass of target analyte added to a blank, sample or sub-sample; used to determine recovery efficiency or for other quality control purposes.

Standard: The document describing the elements of laboratory accreditation that has been developed and established within the consensus principles of standard setting and meets the approval requirements of standard adoption organizations procedures and policies. (TNI)

Standard Operating Procedures (SOPs): A written document which details the method for an operation, analysis, or action, with thoroughly prescribed techniques and steps. SOPs are officially approved as the methods for performing certain routine or repetitive tasks. (TNI)

Storage Blank: A blank matrix stored with field samples of a similar matrix (volatiles only) that measures storage contribution to any source of contamination.

Surrogate: A substance with properties that mimic the analyte of interest. It is unlikely to be found in environment samples and is added to them for quality control purposes.

Surrogate compounds must be added to all samples, standards, and blanks, for all organic chromatography methods except when the matrix precludes its use or when a surrogate is not available. Poor surrogate recovery may indicate a problem with sample composition and shall be reported to the client whose sample produced poor recovery. (QAMS)

Systems Audit (also Technical Systems Audit): A thorough, systematic, qualitative on-site assessment of the facilities, equipment, personnel, training, procedures, record keeping, data validation, data management, and reporting aspects of a total measurement system. (EPA-QAD)

Technical Director: A member of the staff of an environmental laboratory who exercises actual day-to-day supervision of laboratory operations for the appropriate fields of accreditation and reporting of results

Technology: A specific arrangement of analytical instruments, detection systems, and/or preparation techniques.

Traceability: The ability to trace the history, application, or location of an entity by means of recorded identifications. In a calibration sense, traceability relates measuring equipment to national or international standards, primary standards, basic physical constants or properties, or reference materials. In a data collection sense, it relates calculations and data generated throughout the project back to the requirements for the quality of the project. (TNI)

Trip Blank: A blank matrix placed in a sealed container at the laboratory that is shipped, held unopened in the field, and returned to the laboratory in the shipping container with the field samples.

Uncertainty: A parameter associated with the result of a measurement that characterizes the dispersion of the value that could reasonably be attributed to the measured value.

Acronyms:

CAR – Corrective Action Report
CCV – Continuing Calibration Verification
CF – Calibration Factor
CFR – Code of Federal Regulations
COC – Chain of Custody
DOC – Demonstration of Capability

1.0 SCOPE AND APPLICATION

1.1 This SOP describes the procedure for the determination of concentrations of polychlorinated biphenyls (PCB) as Aroclors and as individual Congeners (see Appendix A) using the methodology prescribed in EPA SW-846 Methods 8082 and 8082A.

1.2 This procedure is applicable to the analysis of aqueous, solid, sediment, biological, and waste/oil samples. When utilized for the analysis of waste/oils, additional cleanup procedures may be required.

1.3 This SOP does not include the procedures for extracting environmental samples. Refer to TestAmerica SOPs PT-OP-001 for aqueous and PT-OP-026 for solid and waste sample preparation procedures.

1.4 Table 1 at the end of this document lists the specific Aroclors that are determined using this procedure and their associated reporting limits (RLs).

1.5 On occasion clients may request slight modifications to this SOP. Any modification to this procedure must be approved by the QA department of the Laboratory or Technical Director, and documented fully in an NCM.

2.0 SUMMARY OF METHOD

2.1 Preparation

The extraction procedure is detailed in SOP PT-OP-001 for aqueous samples and PT-OP-026 for solids matrices and wipes.

Extract clean-up procedures are addressed in SOP PT-OP-028.

2.2 Analysis

Samples are analyzed using a gas chromatograph with dual electron capture detectors (ECDs). Specific Aroclor mixtures are identified by the pattern of peaks compared to chromatograms of reference standards. The concentrations of Aroclors in the sample extract are determined using an internal standard calibration.

3.0 DEFINITIONS

3.1 Polychlorinated biphenyls (PCBs): PCBs are a class of organic compounds with 1 to 10 chlorine atoms attached to biphenyl, with a general chemical formula of $C_{12}H_{10-x}Cl_x$. There are 209 possible congeners.

3.2 Aroclor: PCBs were produced as technical mixtures by the chlorination of biphenyl. Production processes were designed to produce mixtures with characteristic chlorine contents. In the United States, most of the PCBs in the environment are in the form of Aroclors, which were produced by Monsanto from the 1930s through 1977. Each Aroclor mixture is identified by a four-digit number, the first two digits of which indicate the number of carbons in the biphenyl ring, i.e., 12, and the second two of which indicate the weight percent of chlorine. For example, Aroclor 1254 has 12 carbons and 54% by weight chlorine. The exception is Aroclor 1016, which has 12 carbons and 41% by weight chlorine.

Each specific Aroclor produces a characteristic gas chromatographic pattern that represents the relative amounts of PCB congeners in the formulation. The

formulation of the mixtures from batch to batch was fairly consistent, but never exactly the same. In almost all cases, the gas chromatogram can be used as a fingerprint to identify the specific Aroclor. Exceptions occurred for Aroclors 1254 and 1221. In each case, at least one batch was produced under different conditions, which resulted in an Aroclor mixture with the same approximate chlorine content, but with a significantly different distribution of congeners. These odd batches of 1254 and 1221 produce chromatographic patterns that are very different from the typical formulations. Standards for these odd batch Aroclors can be used to aid in the qualitative identification of Aroclors in environmental samples.

3.3 TALS: TestAmerica Laboratory Information Management System

3.4 NCM: Non-Conformance Memo – a system within TALS for documenting and communicating QC failures or anomalies encountered during sample receipt, preparation or analysis.

3.5 Please see the glossary of the TestAmerica Pittsburgh Quality Assurance Manual (PT-QA-M-001) for additional definitions.

4.0 INTERFERENCES

4.1 Hydrocarbons can co-elute and thereby mask the Aroclor pattern. The laboratory uses acid cleanup with concentrated sulfuric acid to remove hydrocarbons from solid and oil sample extracts, and for water samples when extracts have noticeable color or whenever there is clear evidence of interferences in the initial sample chromatograms. Acid cleanup removes low-to-medium molecular weight polar organic interferences from sample extracts. Detailed instructions for performing acid cleanup are provided in SOP PT-OP-028.

4.2 Sulfur will interfere and can be removed using procedures described in SOP PT-OP-028.

4.3 Carboprep 90 Cleanup – This method may be performed to remove potential interference prior to analysis if the sample extract is colored.

NOTE: When the Carboprep Cartridge Clean-up Method is used, the recovery of the TCMX surrogate is poor.

4.3.1 Cartridge Method

4.3.1.1 Place approximately 2 ml of sample extract into a test tube and mark the sample volume on the tube.

4.3.1.2 Condition the cartridge by adding 2 ml of methylene chloride and allowing it to drip through the cartridge. Do not allow the cartridge packing to go dry in this or any subsequent step, until the final rinse has been completed.

4.3.1.3 Add 2 ml of hexane/methylene chloride (80%/20%) mixture and allow it to drip through the cartridge until almost empty.

4.3.1.4 Add the sample extract to the cartridge and place the test tube under the cartridge to collect the liquid as it drips through.

4.3.1.5 Rinse 3 times with 2 ml aliquots of hexane/methylene chloride (80%/20%) mixture, while not allowing the cartridge to go dry. After the final rinse, use a pipette bulb to force out all of the remaining liquid in the cartridge.

4.3.1.6 Concentrate the sample extract back down to the original volume according to the mark on the test tube. The extract is now ready for analysis.

4.3.2 Quick Method

4.3.2.1 Add a half scoop of Carboprep 90 to approximately 2 ml of sample extract. Swirl for about one minute and allow the extract to settle.

4.3.2.2 Add a half scoop of Copper Granules to 1 mL of sample or a whole scoop to 2 mL of sample, cap the vial and shake vigorously for 2 minutes.

4.3.2.3 Pipette out an aliquot of extract and filter through a 0.45 µm syringe filter. The extract is now ready for analysis.

4.4 Contamination by carryover can occur when a low concentration sample is analyzed after a high concentration sample. Carryover may also occur with a positive or negative interferrant as well as a target analyte. Any samples analyzed after a samples with high concentrations of target analytes, or high recovery of IS or surrogate compounds, which show the possible effects of carryover must re-analyzed.

4.5 Interferences in the GC analysis arise from many compounds amenable to gas chromatography that give a measurable response on the electron capture detector. Phthalate esters, which are common plasticizers, can pose a major problem in the determinations. Interferences from phthalates are minimized by avoiding contact with any plastic materials.

5.0 SAFETY

5.1 Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use.

5.2 It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.3 Specific Safety Concerns and Requirements

5.3.1 Eye protection that protects against splash, laboratory coat, and nitrile gloves must be worn while handling samples, standards, solvents, and reagents. Disposable gloves that have been contaminated must be removed and discarded; non-disposable gloves must be cleaned immediately.

5.3.2 The gas chromatograph contains zones that have elevated temperatures. The analyst needs to be aware of the locations of those zones, and must cool them to room temperature prior to working on them.

5.3.3 There are areas of high voltage in the gas chromatograph. Depending on the type of work involved, either turn the power to the instrument off, or disconnect it from its source of power.

5.3.4 All ^{63}Ni sources shall be leak tested every six months, or in accordance with the manufacturer's general radioactive material license. All ^{63}Ni sources shall be inventoried every six months. If a detector is missing, the TestAmerica Denver Radiation Safety Officer and the TestAmerica Corporate EH&S Director shall be immediately notified and a letter sent to the Colorado Department of Public Health and Environment.

5.4 Primary Materials Used

The following is a list of the materials used in this method, which have a serious or significant hazard rating. This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material (1)	**Hazards**	**Exposure Limit** (2)	**Signs and Symptoms of Exposure**
Acetone	Flammable	1000 ppm (TWA)	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Hexane	Flammable Irritant	500 ppm (TWA)	Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Vapors may cause irritation to the skin and eyes.
Methylene Chloride	Carcinogen Irritant	25 ppm (TWA) 125 ppm (STEL)	Causes irritation to respiratory tract. Has a strong narcotic effect with symptoms of mental confusion, light-headedness, fatigue, nausea, vomiting, and headache. Causes irritation, redness and pain to the skin and eyes. Prolonged contact can cause burns. Liquid degreases the skin. May be absorbed through skin.
Hydrogen Gas	Explosive	None	The main hazard is flammability. Exposure to moderate concentrations may cause dizziness, headache, nausea, and unconsciousness. Exposures to atmospheres less than 8 to 10% oxygen will bring about sudden unconsciousness, leaving individuals unable to protect themselves. Lack of sufficient oxygen may cause serious injury or death.

(1) Always add acid to water to prevent violent reactions.
(2) Exposure limit refers to the OSHA regulatory exposure limit.

6.0 EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 Instrumentation

6.1.1 A gas chromatographic system with dual columns and dual ECD (^{63}Ni) detectors, and a data system capable of measuring peak area and/or height.

6.2 Supplies

6.2.1 Columns

- Primary Column: RTX-CLP1, 30 m x 0.53 mm id, 0.5 µm coating.
- Secondary Column: RTX-CLP2, 30 m x 0.53 mm id, 0.42 µm coating.
- Additional columns that can be used for confirmation include 30m x 0.53mm id MR1, MR2, RTX5, RTX50 or RTX-1701.

6.3 Autosampler vials, crimp caps with PTFE-faced septa

6.4 Microsyringes, various sizes, for standards preparation, sample injection, and extract dilution

7.0 REAGENTS AND STANDARDS

7.1 The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

7.2 Reagents

7.2.1 Acetone, 99.4% for organic residue analysis

7.2.2 Hexane, pesticide grade.

7.2.3 Carrier Gas: ≥ 99.99999% pure hydrogen

7.2.4 Make-up Gas: ≥ 99.99980% pure nitrogen

7.3 Standards

7.3.1 Stock Standards

7.3.1.1 All standards must be refrigerated at >0.0 ºC but ≤6.0 ºC. All stock standards must be protected from light. Stock standard solutions should be brought to room temperature before using.

7.3.1.2 Stock standards are monitored for signs of degradation or evaporation. The standards must be replaced annually from the date of receipt or earlier if the vendor indicates an earlier date.

7.3.1.3 Dilutions from stock standards cannot have a later expiration date than the date assigned to the parent stock solutions. The standards must

be replaced at least every six months, or sooner, if comparison with check standards indicates a problem.

7.3.2 PCB, Surrogate and Internal Standard Stock Calibration Standards

7.3.2.1 Stock A

For each of the Aroclors listed in Table 1, a commercially prepared stock standard solution is obtained. Each stock standard contains the specific Aroclor in isooctane at a concentration of 1,000 µg/mL. (Note: At times, specific Aroclor stock standards may also be purchased at various concentration levels, for example 2nd source stock standards are purchased at 200 ug/mL concentration.)

7.3.2.2 Surrogate Stock B

A commercially prepared stock standard solution is obtained that contains the surrogate compounds tetrachloro-m-xylene (TCMX) and decachlorobiphenyl (DCB) in acetone, each at a concentration of 200 µg/mL.

7.3.2.3 Internal Standard Stock Standard

A commercially prepared stock standard solution is obtained that contains the internal standard compound, 1-bromo-2-nitrobenzene, at a concentration of 1000 ug/mL.

7.3.3 Intermediate and Working Level Calibration Standard Solutions

7.3.3.1 Stock C (Level 7 Calibration) Standard Solutions

A Stock C standard solution is prepared for the various Aroclors or combination of Aroclors as summarized in the following table. In each case, the Stock C standard solution is also the highest concentration (i.e., Level 7) calibration standard.

Stock C	**Recipe**	**Conc. (µg/mL)**	**Final Volume (mL)**	**Final Concentrations (µg/mL)**	
AR1660	0.1 mL of Aroclor 1016 Stock A 0.1 mL of Aroclor 1260 Stock A	100	10	Aroclor 1016 Aroclor 1260	4.0 4.0
		200	10	TCMX	0.2
	0.2 mL of surrogate Stock B	200	10	DCB	0.2
AR2154	0.125 mL of Aroclor 1221 Stock A	1000	250	Aroclor 1221	0.5
	0.125 mL of Aroclor 1254 Stock A	1000	250	Aroclor 1254	0.5
AR3262	0.125 mL of Aroclor 1232 Stock A	1000	250	Aroclor 1232	0.5
	0.125 mL of Aroclor 1262 Stock A	1000	250	Aroclor 1262	0.5
AR4268	0.125 mL of Aroclor 1242 Stock A	1000	250	Aroclor 1242	0.5
	0.125 mL of Aroclor 1268 Stock A	1000	250	Aroclor 1268	0.5
AR1248	0.125 mL of Aroclor 1248 Stock A	1000	250	Aroclor 1248	0.5

7.3.4 AR1660 Calibration Levels

7.3.4.1 A total of 7 calibration standards are prepared for AR1660 as summarized in the following table. As needed, the following table can be used to prepare calibration standards for any of the Aroclors, but only the

AR1660 calibration standards include the surrogates. In all cases, measured volumes of the Stock C standard are diluted using pesticide-grade hexane to the final volume indicated in the following table.

Level	Volume of Stock C Used (mL)	Final Volume (mL)	Final PCB Conc (µg/mL)	Final Surrogate Conc (µg/mL)*
1	0.01	100	0.01	0.0005
2	0.10	100	0.10	0.005
3	0.25	100	0.25	0.0125
4 (CCV)	1.0	200	0.50	0.025
5	2.0	200	1.0	0.050
6	2.0	100	2.0	0.100
7	4.0	100	4.0	0.200
*Surrogates are in the AR1660 calibration solutions only. None of the other Aroclor calibration solutions contain the surrogate compounds.				

7.3.5 Working Single-Point PCB Calibration Standards

The Level 4 standard in the table above is used for single-point calibrations of the individual Aroclors. These standards are also used as pattern recognition standards.

7.4 Second-Source Standards for Initial Calibration Verification (ICV)

These standards are purchased from a vendor different from the one that supplied the stock calibration standards.

7.4.1 Second-Source Stock A Aroclor Standard Solutions

Commercially prepared solutions in pesticide-grade hexane (or isooctane) are routinely obtained for Aroclors 1016 and 1260. The Aroclor concentration in each solution is 200 µg/mL. Additionally, a second source standard is obtained for all other Aroclors.

7.4.2 Second-Source Working Level Standards

The working level second-source ICV standard is prepared by combining 0.5 mL of Aroclor 1016 Stock A' and 0.5 mL of Aroclor 1260 Stock A' diluting to a final volume of 200 mL with pesticide-grade hexane. This results in a concentration of 0.5 µg/mL for each of the Aroclors. Note: Surrogates are not added to any 2nd source working level standards.

7.5 Continuing Calibration Verification Standard (CCV), 0.5 µg/mL

The working CCV solution is the same as the Level 4 initial calibration standard, as shown in the table in Section 7.3.4.1.

7.6 Laboratory Control Standard (LCS) Spiking Solution (AR1660)

7.6.1 The LCS/MS spiking solution is prepared and used as part of the scope of the organic preparation SOP PT-OP-001. The following information is provided for reference only.

7.6.2 The working LCS spike solution is prepared in a volumetric flask by combining 1 mL of the Aroclor 1016 Stock standard (10,000 ug/ml) and 1 mL of the Aroclor 1260 Stock standard (10,000 ug/ml), and diluting to a 250 mL final volume with acetone. The final concentration of each Aroclor is 40.0 µg/mL.

7.7 Matrix Spike (MS) Spiking Solution:

The working matrix spike solution is the same as the LCS spike solution. The MS duplicate (MSD) is prepared in the same way using a third aliquot of the selected sample.

Matrix Spike and LCS Solutions		
Analyte Group	Matrix spike Solution ID	Volume added in mL
AR1660	40 ug/mL PCB Spike	1.0 - waters
		0.5 - soils
		0.025 - low-level waters
		0.025 – low-level soils
		1.0 – tissues (40 mL F.V.)
		0.5 – tissues (20 mL F.V.)

7.8 Surrogate Spike Solution

7.8.1 Stock Surrogate Spike Solution: A commercially prepared solution containing 200 µg/mL each of decachlorobiphenyl (DCB) and tetrachloro-m-xylene (TCMX) in acetone is purchased.

7.8.2 Working Surrogate Spike Solution: Samples are spiked with the surrogate compounds during sample preparation, which is described in the organic preparation SOP. The following information is provided for reference only.

7.8.3 The working surrogate spike solution is prepared in a volumetric flask by adding 1.6 mL of the DCB (1000 ug/mL) stock surrogate spike solution, 0.80 mL of the TCMX (2000 ug/mL) stock surrogate spike solution and diluting to a final volume of 2000 mL with acetone. The surrogate compounds are added to all field and QC samples as follows:

Surrogate Spiking Solutions		
Analyte Group	**Surrogate Spike Solution ID**	**Volume added in mL**
PCB Aroclors	0.8 ug/mL DCB/TCMX	1.0 - Waters
		1.0 - Tissues (40 mL F.V.)
		0.5 - Tissues (20 mL F.V.)
		0.5 - Solids
	0.2 ug/mL DCB/TCMX	0.1 - low-level waters
		0.1 - low-level soils

7.9 Internal standard

7.9.1 Stock - A commercially prepared stock standard solution is obtained that contains the internal standard compounds, 1-bromo-2-nitrobenzene and BZ-205, at concentrations of 1000 ug/ml and 100 ug/ml respectively.

7.9.2 A working standard for the internal standard, 1-bromo-2-nitrobenzene and BZ-205, is prepared at a concentration of 10 ug/ml. This standard is added to all samples and standards to result in a final concentration of 0.1 ug/ml (20 ul of 1 ug/ml to 200 ul; 10 ul to 100 ul; etc.) after any cleanups or dilutions that may be necessary but before injection.

7.10 Aroclor mixes

The following Aroclors can be analyzed together for calibration and calibration

verification: 1016/1260, 1221/1254, 1232/1262, 1242/1268. If standards are mixed

together, concentrations need to be taken into account (initial concentrations and

final volumes). A calibration curve will be analyzed for 1660 and midpoint

standards will be analyzed for all other Aroclors.

7.11 RT standard

It is an option to make a multi Aroclor standard for the purposes of the daily RT update.

8.0 SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1 Water samples are collected in pre-cleaned amber glass bottles fitted with a Teflon-lined caps. To achieve routine reporting limits, a full one liter of sample is required for regular level extraction and 250mL for LVI extraction*. Because the entire sample volume is used for extraction, additional bottles are needed to satisfy the requirements for matrix spike and matrix spike duplicate analyses.

8.2 Soil samples are collected in 8-ounce, wide-mouth jars with a Teflon-lined lid.

Matrix	Sample Container	Preservation	Extraction Holding Time	Analysis Holding Time	Reference
Waters	Amber glass	Cool >0.0 but ≤6.0°C	1 year	1 year from extraction	40 CFR Part 136.3
Soils	Glass	Cool >0.0 but ≤6.0°C	14[1] Days	40[1] Days from extraction	N/A
Tissues	Borosilicate glass, PTFE, quartz, aluminum foil	Freeze at < - 10°C can be stored this way for 1 year prior to extraction	14 Days from date of thawing	40 Days from extraction	PSEP [2]

[1] Some states will accept a 1 year holding time from sampling to extraction and from extraction to analysis for Solid samples. Consult the Project Manager or the QA Department for specific project requirements before exceeding 14/40 days.

[2]This maximum holding time is also recommended by the PSEP (1990). The California Department of Fish and Game (1990), and the USGS National Water Quality Assessment Program (Crawford and

Luoma, 1993) recommend a more conservative maximum holding time of 1 year at < -10℃ for dioxins/furans. NOAA recommends a maximum holding time of 3 months.

*NOTE: LVI cannot be used for samples from South Carolina. The 1 Liter bottles must be used for sampling.

9.0 QUALITY CONTROL

9.1 Refer to the TestAmerica Pittsburgh QC program document (PT-QA-021) for further details on criteria and corrective actions. Refer to "project checklist" for project specific requirements. More stringent project-specific requirements will supersede the requirements presented in this section when there is a written agreement between the laboratory and the client, and the source of those requirements should be described in the project documents. Project-specific requirements are communicated to the analyst via special instructions in the LIMS.

9.2 Any QC result that fails to meet control criteria must be documented in a Nonconformance Memo (NCM). The NCM is approved by the supervisor and then automatically sent to the laboratory Project Manager by e-mail so that the client can be notified as appropriate. The QA group also receives NCMs by e-mail for tracking and trending purposes. The NCM process is described in more detail in SOP PT-QA-016. This is in addition to the corrective actions described in the following sections.

9.3 If dual column reporting is required, the choice of which column to report the QC from is made in the same manner as for the associated samples.

9.4 The following Quality Controls are required:

Quality Controls	Frequency	Acceptance Limits
Initial Calibration: Minimum 5 points for 1016/1260, One point for all other Aroclors Minimum 6 points for Congeners	Every 6 months, or more often as needed	Average RF: ≤ 20%RSD Linear Regression: Linear Correlation Coefficient ≥0.990 and intercept <1/2 RL
ICV (second source)	After each ICAL	≤ 20%D (80-120% recovery)
CCV[1]	Beginning of run and every 20 samples	8082 ≤ 15%D (85-115% recovery) 8082A ≤ 20%D (80-120% recovery)
RT Windows	With each ICAL (mid-point updated daily with CCVIS)	± 3X SD / ± 0.01 min
Internal Standard (IS)	All standards, samples, and QC	50 – 150% of the response in mid-level calibration standard
Method Blank (MB)	1 per preparation batch	<RL
Laboratory Control Sample (LCS)	1 per preparation batch	Statistical control limits are maintained in TALS.
Matrix Spike (MS)	1 per preparation batch	

Quality Controls	Frequency	Acceptance Limits
		Statistical control limits are maintained in TALS. MS is not used for batch control.
Matrix Spike Duplicate (MSD)	1 per preparation batch	Statistical control limits are maintained in TALS. MSD is not used for batch control.
Surrogates	All samples and QC	Statistical control limits are maintained in TALS.
Dual column agreement	All positive results	40% RPD (see section 11.4 for reporting instructions)

[1]If the analysis includes the use of internal standards, a closing CCV is not required at the end of the analytical run.

9.5 Method blank

9.5.1 A method blank (MB) is prepared and analyzed with each batch of 20 or fewer samples. The method blank consists of reagent water (for aqueous sample batches) or 50:50 sodium sulfate : magnesium sulfate mixture (for solid sample batches) to which the surrogate compounds are added (see SOP PT-OP-001 or PT-OP-026). The method blank is subject to the entire extraction, cleanup and analysis process. The method blank must be analyzed daily prior to sample analysis to demonstrate that the chromatographic system is contaminant free.

9.5.2 The method blank must not contain any analyte of interest at or above the reporting limit (RL). For analytes detected above the MDL, all associated results will be reported with B qualifiers. If the MB is found to be contaminated above the RL, the sample batch must be re-extracted / reanalyzed unless one of the following criteria is met:

- Evaluate the associated sample results. If sample results are non-detect for the Aroclor found in the MB, results may be reported using the “Method Blank – Report, ND” NCM.
- If the associated sample concentrations are >10x the MB concentration, results for these samples may be reported using the “Method Blank – Report, 10X” NCM.
- If neither of the above situations exists, and re-extraction is not possible due to limited sample volume or holding time, the lab must notify the Project Manager. Instructions must be sought from the client on how to proceed with reporting these results. Results that are reported must be properly qualified and an NCM created to document the situation for the case narrative.

9.6 Laboratory Control Sample (LCS)

9.6.1 One LCS is prepared and analyzed with each batch of 20 or fewer samples. The LCS is prepared as described in Section 7.6, using the same matrix as for the MB. The LCS is subject to the entire extraction, cleanup and analysis process.

9.6.2 The LCS recovery must be within the established control limits. The laboratory's standard control limits are set at ± 3 standard deviations around the historical mean, unless project requirements dictate otherwise. Current control limits are maintained in the LIMS. Unless otherwise requested by the client, the PCB LCS contains only Aroclors 1016 and 1260.

9.6.3 For batches that include samples from South Carolina, the LCS control limits are static at 70-130%.

9.6.4 Laboratory generated Control Limits are maintained in TALS and can be provided upon request.

9.6.5 If any analyte is outside the control limits in the LCS, the batch must be re-extracted / reanalyzed unless the following criterion is met:

- If the LCS recovery is above the upper control limit and sample results are non-detect, those associated sample results may be reported with the appropriate qualifier and using the “LCS/LCSD - %R High” NCM.
- If the above situation does not exist, and re-extraction is not possible due to limited sample volume or holding time, the lab must notify the Project Manager. Instructions must be sought from the client on how to proceed with reporting these results. Results that are reported must be properly qualified and an NCM created to document the situation for the case narrative.

9.7 Matrix Spike (MS) and Matrix Spike Duplicate Samples (MSD)

9.7.1 One MS/MSD pair is required with each analytical batch of 20 or fewer samples. Note that some programs (e.g., North Carolina and South Carolina) require preparation and analysis of an MS/MSD pair at a 10% frequency. This shall be noted in the project when required. Preparation of the MS is described in Section 7.7. The MSD is another aliquot of the sample selected for the MS that is spiked in the same manner as the MS.

9.7.2 The MS and MSD recoveries must fall within the established LCS control limits. The relative percent difference (RPD) between the MS and MSD must be less than the established limit, which is based on statistical analysis of past results, unless otherwise dictated by project requirements. Current control limits are maintained in the LIMS.

Laboratory generated Control Limits are maintained in TALS and can be provided upon request.

9.7.3 If analyte recovery or RPD falls outside the acceptance range, but the associated LCS recovery is in control, and all other QC criteria (e.g., continuing calibration verification) are met, then there is no evidence of analytical problems. This may indicate that the sample matrix itself has an adverse effect on recovering the analyte.

- If a matrix effect is suspected, the parent sample is qualified appropriately, and results are reported using the "MS/MSD - %R, LCS Pass" NCM.
- If the recovery for any component is outside control limits for both the MS and the LCS, the laboratory is out of control and corrective action must be taken. Refer to section 9.6.4.
- If an MS/MSD is not possible due to limited sample, then an LCS duplicate (LCSD) may be analyzed to monitor batch precision.

9.7.4 The MS/MSD must be analyzed at the same dilution level as the parent sample, unless the matrix spike components would then be above the calibration range. In this case, would require a dilution greater than the parent sample to bring the spiked compounds within the calibration range.

9.7.4.1 For PCB analysis, the matrix spike added is diluted to concentrations below the RL at a dilution of 40X. MS/MSD that are diluted above 40X must be reported with a "D" qualifier on the spiked compounds to indicate that recovery is not able to be accurately calculated.

9.7.4.2 If the parent sample concentration is >4X, it may not be possible to accurately calculate %recoveries. Results will be reported with the "MS/MSD – High Targets" NCM.

9.8 Surrogates

9.8.1 Each field sample, QC sample, and calibration standard, is spiked with surrogate compounds decachlorobiphenyl (DCB) and tetrachloro-m-xylene (TCMX). The surrogate spike solution is prepared as described in Section 7.8.

9.8.2 For field samples and batch QC, the surrogate recoveries must be within the established control limits, which are set at ± 3 standard deviations around the historical mean, unless project requirements dictate otherwise. Surrogate recovery limits are maintained in TALS.

9.8.2.1 Surrogate recoveries for both DCB and TCMX in the MB and LCS both must pass on at least one column. If the recovery of the surrogates in MB or LCS's is outside of the control limits, check for calculation or instrument problems.

- Surrogate recoveries (one or both) outside of control limits on both columns for the MB or LCS require re-preparation and reanalysis of the entire preparation batch.

9.8.2.2 For field samples, surrogate recovery is calculated and reported for both DCB and TCMX. At least one surrogate must pass on the one column from which Aroclors are identified and reported, and that column must have a passing CCV.

9.8.2.3 For CCV standards, Aroclors 1016 and1260 and surrogates must pass on the reporting column, for the data to be considered reportable.

9.8.2.4 If both surrogates fail on both columns for a sample, and matrix interference is not obvious from the initial analysis, it is only necessary to re-prepare and reanalyze a sample once to demonstrate that poor surrogate recovery is due to matrix effects, as long as the extraction/instrument system is proven to be working properly according to the batch and instrument QC.

9.8.2.5 For PCB analysis, the surrogate spike added is diluted to concentrations below the RL at a dilution of 40X. Samples that are diluted above 40X must be reported with a "D" qualifier on the surrogates to indicate that recovery is not able to be accurately calculated.

9.9 Initial Calibration

9.9.1 See section 10.3 below for initial calibration options and evaluation requirements.

9.9.2 A full calibration (minimum 5 points) is required on both columns for Aroclor 1016 and 1260 and the two surrogates plus internal standards. A single point is used for all other Aroclors.

9.9.3 Each peak in the Aroclor (a minimum of 5 peaks is required for all Aroclors, except 1221, which requires a minimum of 3 peaks) is intergrated using peak height.

9.9.4 The calibration must be verified by the analysis of a second source standard (ICV) near the mid-point of the calibration range. The %Drift/Difference for this standard must be $\leq$ 20% from the ICAL. (The response for each individual peak for the Aroclors in the ICV standard must be within ± 20.0% of the expected value.

If the ICV response does not meet this limit, repeat the ICV analysis once with a freshly made standard. If failure repeats, the initial calibration and ICV standards must be prepared fresh and calibration repeated.

9.10 Continuing Calibration Verification (CCVIS)

NOTE: It is not necessary to run a CCV standard at the beginning of the sequence if samples are analyzed immediately after the completion of the initial calibration and ICV.

9.10.1 A mid-level calibration standard of 1016/1260 is analyzed as the continuing calibration verification (CCVIS) standard at the beginning of the analytical sequence, and after every 20 samples (all injections except solvent blanks count as samples), or every 12 hours, whichever is more frequent. Depending on the type of samples, it may be advisable to analyze verifications more frequently in order to minimize reruns. If 12 hours elapsed since the last CCV was analyzed, a new sequence is started with a fresh CCV.

9.10.2 A mid-range CCV standard of each Aroclor must be analyzed at least every 24 hours, for retention time updating.

9.10.3 If Aroclors other than 1016 or 1260 are detected in any sample, a CCV of the associated Aroclor(s) must be analyzed within 12 hours of the sample and pass criteria in order for the sample data to be reported. If a CCV is not run within 12 hours of the sample, or if the CCV does not meet the method CCV criteria, the sample must be re-analyzed along with a passing CCV for that compound. CCV's of other Aroclors may be run every 20 samples/12 hours along with the 1016/1260 CCVs in a routine analysis sequence to meet this requirement. If the analysis includes the use of internal standards, a closing CCV is not required at the end of the analytical run.

9.10.4 Acceptance criteria for CCVs is < 15%D for method 8082 and <20%D for 8082A. All Aroclors (each individual peak) and surrogates must meet these recovery limits on both columns, unless only reporting from one column. If a CCV does not meet the acceptance criteria explained above, associated samples must be re-analyzed unless one of the following conditions is met:

- If the CCV (or individual peak) %D fails high, >15.0% for 8082 or >20.0% for 8082A, and the sample results are ND for that compound, the data may be reported with the appropriate qualifier and the "CCV - %D, High, Samples ND" NCM.
- If the CCV % D fails low, and samples results are ND, then a low level standard can be analyzed to prove that the instrument is sensitive enough to call the sample "Not Detected" and the sample can be reported. This low level standard must be analyzed after all batch samples to prove that sample matrices have not affected the ability to recover compounds of interest at the reporting limit. Results may be reported with proper qualification and using the "CCV – Low Biased, ND, RL Check Passes" NCM.
- If the CCV fails on the non-reporting, or confirmation, column, and that failure does not exceed 40%D, results may be reported without qualification.
- If a continuing batch CCV fails, and there is evidence that the sample matrix has affected the column performance, samples must be rerun once to confirm this affect. Results may be reported from the first or second analysis, with proper qualification and using the "CCV - %D, Capping, RR Confirms" NCM.
- If more than 5 (or 3 for 1221) peaks are used for

identification/quantitation, and a single peak fails to meet CCV criteria, that peak may be removed from the quantitation for the affected CCV and all associated samples and QC, as long as the minimum number of peaks remain.

9.11 Retention Time (RT) Windows

9.11.1 Absolute retention times are used for the identification of PCBs as Aroclors. However, in addition to retention times, peak patterns play a large role in the identification of Aroclors.

9.11.2 The center of the retention time (RT) window shall be updated based on the middle level in the initial calibration or the first CCV (CCVIS) in the daily analytical sequence, whichever is more recent,.

9.11.3 Before establishing windows, make sure the GC system is within optimum operating conditions. Evaluate the deviation from expected RT for each analyte in at least three CCV and/or LCS samples spread over at least 72 hours.

- If three days of analytical data are not available, use a default RT window of 0.010 minutes. At the end of the batch, evaluate all CCVs and LCS in the batch. If necessary, widen the window such that all analytes fall within the RT window. Reprocess the batch using the new RT windows.
- Multiply the maximum deviation from the set by 1.5. This is the retention time window, unless the result is less than 0.010 minute, in which case the window is set at 0.010 minute.
- Determine the retention time (RT) windows for the 3-5 major peaks selected for each Aroclor. The AR1016 windows will be used to establish retention time windows for PCBs AR1221, AR1016, AR1232, AR1242, and AR1248. The AR1260 windows will be used to establish retention time windows for PCBs AR1254, AR1260, AR1262, and AR1268.
- Retention time windows for analytes of interest must not overlap.

9.11.4 Evaluate the retention time windows on an ongoing basis. The center of the RT window is updated on the first CCV (CCVIS) of the day. All analytes for all subsequent CCVs, LCS and matrix spikes must fall within the RT window, except as discussed below.

Matrix spike analytes may fall outside the RT window if there is a large, non-target peak co-eluting, or overlapping, with the analyte in the matrix.

9.11.5 If any analyte falls outside the RT window in CCV, LCS or matrix spike (except as discussed above for matrix spikes), then the RT window for that analyte shall be widened to the minimum degree required for the analyte to fall within the RT window. All samples in the batch shall be reprocessed with the new RT window, and the wider RT window shall remain in place for subsequent batches.

9.11.6 Retention time windows should be reliably narrower than +/- 0.03

minute. If RT windows wider than this are necessary, the instrument should be evaluated and maintenance performed as needed. Subsequent to maintenance, RT windows shall be narrowed to the extent that is consistent with the data obtained and the foregoing requirements.

9.11.7 The laboratory must calculate retention time windows for each analyte on each GC column and whenever a new type of GC column is installed. The data must be retained by the laboratory and available for review.

9.12 Control Limits: In-house historical control limits must be determined for surrogates, matrix spikes, and laboratory control samples (LCS). These limits must be reviewed at least annually. The recovery limits are mean recovery +/- 3 standard deviations, unless that limit is tighter than the calibration criteria, in which case limits may be widened. Refer to policy PT-QA-021 for more details.

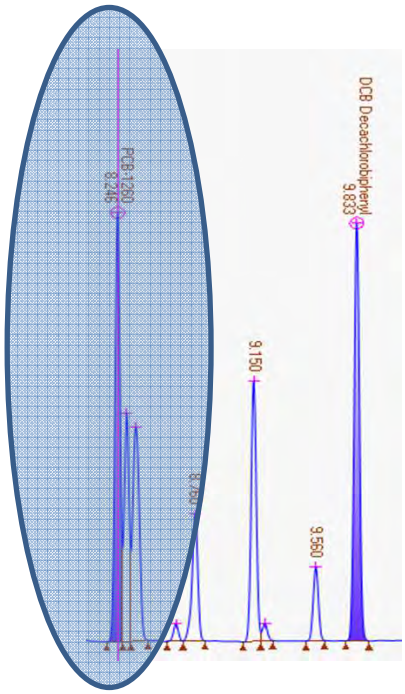
9.12.1 Surrogate and matrix spike recoveries will be reported unless the dilution is more than 40X.

9.13 Percent Moisture

9.13.1 Analytical results may be reported as dry or wet weight, as required by the client. Percent moisture must be determined on a separate portion of the sample if results will be reported based on dry weight.

9.14 Internal Standard Criteria

9.14.1 If the internal standard response in the continuing calibration is more than 150% or less than 50% of the response in the mid-level calibration standard, the chromatographic system must be inspected for malfunctions and corrected. Reanalysis of samples analyzed while the system was malfunctioning is required.



9.14.2 Any samples or standards that do not meet the internal standard criteria of > 50% and <150% of the response of the mid-level calibration standard must be evaluated for validity. Samples that are reported with internal standard exceedances must have documentation supporting matrix effect. Where the matrix effect is well established it may be reported with narration, otherwise the samples must be reanalyzed to confirm matrix effect is required. If the internal standard exceedance is deemed to be due to an instrumental problem, instrument maintenance will be done and all affected samples must be reanalyzed after the problem is corrected.

9.15 Resolution Check requirement

9.15.1 The circled triplet of peaks in the figure below is observed towards the end of the 1260 pattern on columns such as CLP 1. Minimum resolution (degree of overlap) requirement between peak 1 / 2 and peak 2 / 3 is <75%. This chromatogram shows overlap of about 50% between peak 2 and 3, and 30% between peak 1 and 2.

9.15.2 Resolution (degree of overlap) is calculated as follows:

[Height of the valley / (Sum of the two peak heights / 2)] x 100%

9.16 Procedural Variations

9.16.1 Any variation in procedure shall be completely documented using a Nonconformance Memo and approved by a supervisor and QA Manager. If contractually required, the client shall be notified. The Nonconformance Memo shall be filed in the project file. The nonconformance is also addressed in the case narrative. Any unauthorized deviations from this procedure must also be documented as a nonconformance, with a cause and corrective action described.

10.0 PROCEDURE

10.1 Sample Preparation

10.1.1 Samples are extracted and prepared for analysis as described in SOPs PT-OP-001 and PT-OP-026. Allow extracts to warm to room temperature before injecting.

10.1.2 If needed, extracts are cleaned up using the procedure in section 4.3 of this SOP or one of the clean-up procedures in SOP PT-OP-028. Any clean-up performed is documented either within the method chain or using an NCM.

10.1.3 Internal standard is added to each extract prior to loading the extract on the instrument for analysis. Add 1µL of Internal Standard Spike (7.9) per 100µL of extract or standard.

10.2 Calibration

Instrument conditions for this method are presented in Table 2.

10.2.1 Use the ChemStation interface to establish instrument operating conditions for the GC.

10.2.2 Raw data obtained by the ChemStation software is transferred to the CHROM DB(database) for further processing. The data analysis method, including peak processing and integration parameters, calibration, RT windows, and compound identification parameters, is set up in the CHROM DB software.

10.2.3 Transfer calibration standard solutions into autosampler vials and load into the GC autosampler. Use the ChemStation software to set up the analytical sequence.

10.2.4 Unprocessed calibration data are transferred to the CHROM DB database for processing. After processing the calibration data, print the calibration report and review it using the calibration review checklist (GC and HPLC Data Review Checklist - ICAL). Submit the calibration report to a qualified peer or the group leader for final review. The completed calibration reports are scanned and stored as Adobe Acrobat files on the Public Drive.

10.2.5 A new calibration curve must be generated initially, after major changes to the system, or when continuing calibration criteria cannot be met. Major changes include installation of new type of column and replacing the ECD detector. Initial Calibration will be performed at least every 6 months.

10.3 Initial Calibration (ICAL)

10.3.1 An initial standard calibration using seven concentration levels of the AR1660 mixture is routinely performed. (At least five calibration levels are required.) Table 3 provides concentration levels for Aroclor 1016, Aroclor 1260, and the surrogate compounds DCB and TCMX.

10.3.2 All initial calibration points must be analyzed without any changes to instrument conditions, and all points must be analyzed within 24 hours.

10.3.3 The calibration curves for Aroclors 1016 and 1260 and the surrogate compounds, relative to the internal standard response, are modeled either as average response factors (RF) or as calibration curves using a systematic approach to selecting the optimum calibration function. PCB's are well established linear responding compounds and an average curve fit should be the norm. Use of linear regression is acceptable, however the individual points should be evaluated to determine if there has been a change in the instrument sensitivity or if there is a potential issue with the standards.

10.3.4 The calibration for each of the other Aroclors (see Tables 1 & 3) is initially determined using a single, mid-level calibration standard. As needed, the laboratory may generate a multi-point calibration for other commonly detected Aroclors, such as 1221, 1254, and 1248. When additional multi-point calibrations are developed for the other Aroclors, a second-source ICV standard is also analyzed, see section 9.9.

NOTE: Samples from sites known to be contaminated with specific Aroclors should be analyzed using a multi-point calibration curve for the identified Aroclors. This information is provided to the analyst through special instructions in the LIMS.

NOTE: Generally, it is NOT acceptable to remove points from a calibration for the purposes of meeting calibration criteria, unless the points are the highest or lowest on the curve AND the reporting limit and/or the linear range is adjusted accordingly. A minimum of five levels must remain in the calibration for a linear regression. The documentation must be retained with the initial calibration. Alternatively, if the analyst believes that a point on the curve is inaccurate, the point may be reanalyzed and the reanalysis used for the calibration.

10.3.5 The high and low standard for the initial calibration of the AR1660 mixture defines the acceptable quantitation range for all of the Aroclors. If a sample extract contains any Aroclor at a concentration that exceeds the upper range of the calibration, then the extract must be diluted and reanalyzed.

10.3.6 Select 5 major peaks (at least 25% peak height of the largest peak in the aroclor) in the analyte pattern (only 3 peaks are usable for Aroclor 1221). The response factors or curves will be generated for each of these major peaks for each Aroclor. The results are based off of an average of the calculated concentrations of these major peaks.

NOTE: A minimum of five accurate peaks must be used to quantify an Aroclor (three peaks for Aroclor 1221).

NOTE: See Appendix A for more details on peak choice and identification of individual Aroclors.

10.4 Internal Standard Calibration

10.4.1 Internal standard calibration involves the comparison of instrument responses from the samples to the responses from the target compounds in the calibration standards. The area (or height) of a peak and the area (or height) of the internal standard in a sample chromatogram is compared to the area (or height) of the peak and the area (or height) of the internal standard in the standard chromatograms that appears at the same retention time. The ratio of the detector response to the concentration of the target analyte in the calibration standard is defined as the response factor (RF) and is calculated as follows:

$$RF = \frac{Ax \times Cis}{}$$

$$\frac{A_{is} \times C_x}{A_x}$$

Where:

A_x = Area (or height) of the peak to be measured

A_{is} = Area (or height) of the peak for the internal standard

C_{is} = Concentration of the internal standard

C_x = Concentration of the peak being measured

NOTE: It is also possible to use the concentration of the standard rather than the mass injected.

10.5 Establishing the Calibration Function

10.5.1 Calibrations are modeled either as average response factors (RF) or as linear regression curves, using a systematic approach to select the optimum calibration function. Start with the simplest model, i.e., average RF, and progress through the other options until calibration acceptance criteria are met. PCB's are well established linear responding compounds and an average curve fit should be the norm. If linear regression is utilized, it is acceptable, however the individual points should be evaluated to determine if there has been a change in the instrument sensitivity or if there is a potential issue with the standards. Different calibration models can be applied to each of the major peaks chosen to represent the Aroclor.

NOTE: Each individual peak used for each Aroclor must meet the calibration acceptance criteria.

10.5.2 Linear Calibration Using Average Response Factor (RF)

The response factor is a measure of the slope of the calibration line, assuming that the line passes through the origin. Under ideal conditions, the factors calculated for each calibration level will not vary with the concentration of the standard. In practice, some variation can be expected. When the variation, measured as the relative standard deviation, is relatively small (e.g., ≤ 20%), the use of the straight line through the origin model is generally appropriate.

The average response factor is calculated as follows:

$$\text{Average RF} = \overline{RF} = \frac{\sum_{i=1}^{n} RF_i}{n}$$

Where:

RF_i = The response factor for the i^{th} calibration level.

n = The number of calibration levels.

The relative standard deviation (RSD) is calculated as follows:

$$RSD = \frac{SD}{\overline{RF}} \times 100\%$$

Where SD is the standard deviation of the average RF, which is calculated as follows:

$$SD = \sqrt{\frac{\sum_{i=1}^{n} \left(RF_i - \overline{RF}\right)^2}{n-1}}$$

10.5.3 Evaluation of the Average Response Factor:

Plot the calibration curve using the average RF as the slope of a line that passes through the origin. Examine the residuals, i.e., the difference between the actual calibration points and the plotted line. Particular attention should be paid to the residuals for the highest points, and if the residual values are relatively large, a linear regression should be considered.

- The RSD for each peak chosen to represent the aroclor must be ≤ 20.0% for both 8082 and 8082A.
- If the %RSD is <20.0% (8082/8082A), alternative curve fits may still be considered.
- If the RSD exceeds the limit, linearity through the origin cannot be assumed, and alternative curve fits must be considered.

10.5.4 Linear Calibration Using Least-Squares Regression (weighted) - Evaluation of the Linear Least-Squares Regression Calibration Function

With an unweighted linear regression, points at the lower end of the calibration curve have less weight in determining the curve than points at the high concentration end of the curve. For this reason, inverse weighting of the linear function is recommended to optimize the accuracy at low concentrations. Note that the August 7, 1998 EPA memorandum "Clarification Regarding Use of SW-846 Methods", Attachment 2, Page 9, includes the statement "The Agency further recommends the use of this for weighted regression over the use of an unweighted regression."

- To avoid bias in low level results, the absolute value of the y-intercept must be significantly less than reporting limit (RL), and preferably less than the MDL.
- Also examine the residuals, but with particular attention to the residuals at the bottom of the curve. If the intercept or the residuals are large, the calibration should be repeated since a higher order regression is not allowed for this method.
- If weighted linear regression is used 1/(Amt) or 1/(Amt)2 a minimum of 5 points are required. The coefficient of determination (r2) must be >

0.990. If the correlation of determination falls below the acceptance limit, linear regression cannot be used and a second-order regression should be attempted.

- If the correlation coefficient falls below the acceptance limit, the linear regression is unacceptable and the calibration should be repeated since a higher order regression is not allowed for this method.
  - For non-detects, reanalysis is not required, and flagging is not required.

10.5.5 Other curve types

Due to the stability of the compounds, non-linear calibration curves (quadratic) and unweighted linear regression curves are not applicable for this method.

10.5.6 Calibration point read-back criteria

Whichever calibration mode above is selected, it should be subjected to an additional check to establish the representativeness of the data that were used to produce it. This check is the refitting of each calibration point response back to the calibration model, or the comparison of the calculated amount of the standard against the expected amount.

- CHROM software provides an Initial Calibration %Drift report which shows the % Error for each calibration point. This report must be reviewed in addition to the %RSD / Linear Response Factor.
- The absolute value of the % Error for each calibration point should be $\leq$ 30%. For the lowest calibration point, the % Error may be $\leq$ 50%.

10.5.7 Removal of calibration points and/or levels

10.5.7.1 Certain analytes that have particularly high or low sensitivity may need to have the high or low calibration points removed in order to optimize the calibration curve. Removal of high or low calibration points is allowed, but the working range of the calibration must be adjusted accordingly. The reporting limit must be supported by the lowest point remaining in the calibration and any samples with concentrations above the highest point in the calibration must be diluted and reanalyzed.

10.5.7.2 Points for individual compounds from the interior levels of the calibration may not be removed. A complete level may be removed if the laboratory can document a clear reason for incorrect response in the standard (for example, analysis of the incorrect level, failure to add internal standards or instrument malfunction).

10.6 Second-Source Initial Calibration Verification (ICV)

10.6.1 Second-source ICV standards are analyzed for all Aroclors. The stock

standards are obtained from a source different than that of the standards used for the calibration. The ICV standards are analyzed immediately following the initial calibration. Refer to section 9.9.4 for acceptance criteria.

10.7 Sample Analysis

10.7.1 An autosampler is used to introduce samples into the chromatographic system by direct injection of 1 or 2 µL of the sample extract.

10.7.2 Samples, standards, and QC samples must be introduced using the same procedure.

10.7.3 All extracts and standards are allowed to warm to room temperature before injection.

10.7.4 Use the ChemStation interface to set up and run the analytical sequence. Sample injection and analysis are automated and may proceed unattended.

10.8 Analytical Sequence

10.8.1 An analytical sequence starts with a minimum five-level initial calibration (ICAL) or a daily calibration verification. The daily run sequence is generated electronically using the ChemStation software.

The following is the typical analytical sequence for routine sample analysis:

Suggested Analytical Sequence		
Initial Calibration	(not required daily)	
Injection No.		
1	Solvent Blank (optional)	
2	Aroclor 2154	Level 4
3	Aroclor 3262	Level 4
4	Aroclor 4268	Level 4
5	Aroclor 1248	Level 4
6	Aroclor 1016/1260	Level 1
7	Aroclor 1016/1260	Level 2
8	Aroclor 1016/1260	Level 3
9	Aroclor 1016/1260	Level 4
10	Aroclor 1016/1260	Level 5
11	Aroclor 1016/1260	Level 6
12	Aroclor 1016/1260	Level 7
13-17	ICV's (2^{nd} source standard of all Aroclors)	
18	Method Blank	
19-38	Sample 1-20 (or 12 hours)	
39	Aroclor 1016/1260	Level 4
At least every 24 hours, counting from the start of the initial calibration or from the start of the last daily calibration, the retention time windows must be updated. CCVs for 1016/1260 must be run every 20 samples or 12 hours, whichever is more frequent. Mid-level standards of any other Aroclors expected to be present in the samples are also injected. For sequences without an initial calibration, start with CCVIS 1660 and CCVs for 1248 and 2154, method blank plus 19 samples, then CCVIS 1660 and CCVs for 3262 and 4268, method blank plus 19 samples. This way all standards are run within 24 hours for RT's and samples with detections other than 1660 have CCVs within 12 hours.		

10.9 When a sample result exceeds the upper calibration range, then that sample extract is diluted to obtain a result in the upper half of the calibration range and reanalyzed. Any samples that were analyzed immediately following the high sample are evaluated for carryover. If the samples had target analyte detections at or above the RL, the samples must be reanalyzed to rule out carryover.

10.10 Upon completion of the analytical sequence, transfer the raw chromatography data to the CHROM DB database for further processing. Review chromatograms online and determine whether manual data manipulations are necessary. All manual integrations must be justified and documented. See CA-Q-S-002 for requirements for manual integration.

10.11 Manual integrations may be processed using an automated macro, which prints the before and after chromatograms and the reason for the change, and attaches the analyst's electronic signature. Alternatively, the manual integration may be processed manually. In the latter case, print both the both the before and after chromatograms and record the reason for the change and initial and date the after chromatogram. Before and after chromatograms must be of sufficient scale to allow an independent reviewer to evaluate the manual integration.

10.12 Compile the raw data for all the samples and QC samples in a batch. The analytical batch is defined as containing no more than 20 samples, which include field samples and the MS and MSD. Perform a level 1 data review and document the review on the data review checklist (GC Data Review Checklist). Submit the data package and review checklist to a peer analyst for the level 2 review. The data review process is explained in SOP PT-QA-018.

11.0 CALCULATIONS / DATA REDUCTION

11.1 Qualitative Identification of Aroclors

Retention time windows are used for identification of Aroclors, but the "fingerprint" produced by major peaks of those analytes in the standard is used in tandem with the retention times for identification. The ratios of the areas of the major peaks are also taken into consideration. Identification may be made even if the retention times of the peaks in the sample fall outside of the retention time windows of the standard, if in the analyst's judgment the fingerprint (retention time and peak ratios) resembles the standard chromatogram. If there are any anomalies in the pattern due to the presence of multiple PCBs or weathering of peaks the analyst should discuss this with another analyst or technical director to come to a consensus about which PCB(s) should be identified. An NCM should be completed indicating the rationale behind the decision made. Sometimes Aroclors 1262 and 1268 are not requested as target analytes. If these patterns are observed, an NCM should be completed informing the project manager of possible PCB detection.

NOTE: See Appendix A for more details on peak choice and identification of individual Aroclors.

11.2 Quantitation of Aroclors

Quantitation of Aroclors is accomplished using 5 major peaks. The peaks must be within the established retention time windows. If there is an interference that affects the accuracy of results, the analyst must use 5 major peaks (3 peaks for Aroclor 1221). The same peaks that are used for sample quantitation must be used for standards and QC quantitation. The concentrations of each of the major peak are averaged for a final concentration result. When using this option, it is appropriate to remove peaks that appear to be co-eluting with contaminant peaks from the quantitation (i.e. peaks that are significantly larger than would be expected from the rest of the pattern or peaks that have been significantly weathered and are smaller than would be expected). This should be done if there are peaks that differ from the others by a factor of 2 to 5 depending on where the results fall within the calibration curve.

11.3 Second column confirmation of Aroclors is always performed and is reported when requested by the client.

11.4 Dual Column Quantitation

11.4.1 Dual column quantitation is routinely performed for PCB analysis and reported as such when requested by the client.

11.4.2 When reporting the analytical results for field samples of dual column analysis, the higher of the two results is normally reported. The result from the second column confirmation is reported if any of the following is true:

- There is obvious chromatographic interference on the initial quantitation column.
- The difference between the result on the initial quantitation column and the result on the second column is > 40% and chromatographic interference is evident.
- A continuing or bracketing standard fails on the initial quantitation column, but is acceptable on the second column. However, if the difference between the initial quantitation column and second column results is > 40% and the initial quantitation column calibration verification fails, then the sample must be evaluated for reanalysis.

11.4.3 Dual Column Results with > 40% RPD:

- If the relative percent difference (RPD) between the responses on the two columns is greater than 40%, the lower of the two results is reported unless there is obvious interference documented on the chromatogram. If the result is < the RL it will be reported as estimated with a “J” flag.
- If there is visible positive interference, e.g., co-eluting peaks, elevated baseline, etc., for one column and not the other, then report the results from the column without the interference with the appropriate data qualifier flag, footnote, and/or narrative comment in the final report.

- If there is visible positive interference for both columns, then report the lower of the two results with the appropriate flag, footnote, and/or narrative comment in the final report.
- If the relative percent difference (RPD) between the results on the two columns is greater than 40%, or if the opinion of an experienced analyst is that the complexity of the matrix is resulting in false positives, the confirmation is suspect and the results are qualified. The RPD is calculated as follows:

$$\%RPD = \frac{|R_1 - R_2|}{1/2(R_1 + R_2)} \times 100\%$$

Where:

R_1 = initial quantitation column result

R_2 = second column result

NOTE: Wisconsin requires when results are greater than the LOQ (RL) and the %RPD between column results is greater than 40%, that the HIGHER of the two results must be reported unless the analyst defensible documents that the higher result is biased due to an interference.

11.5 Calibration Range and Sample Dilutions

11.5.1 If the concentration of any analyte exceeds the working range as defined by the calibration standards, then the sample must be diluted and reanalyzed. Dilutions should target the most concentrated analyte in the upper half (over 50% of the high level standard) of the calibration range. Samples that were analyzed immediately following the high sample must be evaluated for carryover. If the samples have results at or above the RL for any analyte, they must be reanalyzed to rule out carryover. It may also be necessary to dilute samples because of matrix interferences.

11.5.2 If the initial diluted run has no hits or hits below 20% of the calibration range, and the matrix allows for analysis at a lesser dilution, then the sample should be reanalyzed at a dilution targeted to bring the largest hit above 50% of the calibration range.

11.5.3 Guidance for Dilutions Due to Matrix Interference

If the sample is initially run at a dilution and only minor matrix peaks are present, then the sample should be reanalyzed at a more concentrated dilution. Analyst judgment is required to determine the most concentrated dilution that will not result in instrument contamination. Ideally, the dilution chosen will make the response of the matrix interferences equal to approximately half the response of the mid-level calibration standard.

11.5.4 Reporting Dilutions
Some programs (e.g., South Carolina) and some projects require reporting of multiple dilutions (check special requirements in LIMS). In other cases, the most concentrated dilution with no target compounds above the calibration range will be reported. If results are reported from a diluted run, the cause for the dilution should be narrated in an NCM. For dilutions greater than 40X report the surrogates diluted out ("D").

11.6 Interferences in Observed in Samples

11.6.1 Dual column analysis does not entirely eliminate interfering compounds. Complex samples with high background levels of interfering organic compounds can produce false positive and/or false negative results. The analyst must use appropriate judgment to take action as the situation warrants.

11.6.2 Suspected Negative Interferences: If peak detection is prevented by interferences, further cleanup should be attempted. Elevation of reporting levels and/or lack of positive identification must be addressed in the case narrative.

11.7 Concentration of Analyte in Sample Extract

11.7.1 Depending on the calibration function used, the concentration of the analyte in the sample extract is calculated as follows (see Section 10 for details on establishing the calibration function):

Average Response Factor: $C_{ex} = \frac{R_x C_{is}}{R_{is} RF}$

Linear Regression: $C_{ex} = A + B\frac{(R_x C_{is})}{R_{is}}$

Where:

Cex = Concentration in the extract, µg/mL

Rx = Response for the analyte

Ris = Response for the internal standard

Cis = Concentration of the internal standard

A = Intercept of linear calibration line

RF = Average response factor

B = Slope of linear calibration line Concentration of Analyte in Original Sample

11.7.2 The concentration of the analyte in the original sample is calculated as follows:

$$C_{sample} = \frac{C_e}{1000\frac{ng}{\mu g}} \times \frac{V_e}{V_s} \times DF$$

Where:

C_{sample} = Concentration of analyte in original sample (µg/L or µg/kg).

C_e = Concentration of analyte in sample extract injected in GC (ng/mL).

$1000\frac{ng}{\mu g}$ = Factor to convert ng/mL to µg/mL.

V_e = Volume of sample extract (mL).

V_s = Volume (or weight) of original sample (L or kg).

DF = Dilution Factor (post extraction dilutions)

11.7.3 Spike Recovery Calculation

$$\%\text{Recovery} = \frac{\text{Measured Concentration}}{\text{Spiked Concentration}} \times 100\%$$

11.7.4 MS/MSD RPD Calculation

$$RPD = \frac{\left|MS - MSD\right|}{1/2\left(MS + MSD\right)} \times 100\%$$

12.0 METHOD PERFORMANCE

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2 Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3 A Method Detection Limit (MDL) Study, as described in the Detection Limits SOP, PT-QA-007, must be performed initially and whenever a significant change is made to the analytical system. The MDL must be re-evaluated from quarterly MDL points at least every 12 months.

12.4 Lower Limit of Quantitation Verification – The lowest calibration standard analyzed establishes the LLOQ or Reporting Limit. The capability to reliably detect this concentration through the preparation, clean-up and analytical procedure is verified through the annual analysis of a standard at the LLOQ/RL. The LLOQ verification shall also be performed whenever significant changes are made to the preparation and/or analytical procedure.

12.4.1 The LLOQ verification standard shall be prepared at a concentration 0.5-2 times the LLOQ/RL, and be taken through all preparation and clean-up methods which samples would be.

12.4.2 The LLOQ verification standard for aqueous matrix shall be prepared using laboratory deionized water and for the solid matrix using clean Ottawa sand. Other clean matrices may be used in addition, for project specific requirements.

12.4.3 The LLOQ shall be verified annually on each instrument used for client sample analysis.

12.4.4 Recovery of each analyte must meet the laboratory established LCS recovery limits ± 20%. (For example, if the LCS recovery limits are 70-130%, the LLOQ verification must meet recovery limits of 50-150%.) Once sufficient points have been generated, LLOQ based statistical limits may be used in place of limits based on LCS recovery.

NOTE: The lower recovery limit for the LLOQ can be no lower than 10%.

12.4.5 If the LLOQ cannot be verified, it will be necessary to raise the RL to a concentration level that can be carried through the preparation and clean-up steps to meet recovery limits.

13.0 POLLUTION CONTROL

13.1 It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

14.0 WASTE MANAGEMENT

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.2 Methylene Chloride in vials. This waste is placed in waste container identified as "Vials & Extracts", Waste #7.

14.3 Flammable solvents in vials. This waste is placed in waste container identified as "Vials & Extracts", Waste #7.

14.4 Waste flammable solvents. This waste is collected in a waste container identified as "Mixed Flammable Solvent Waste", Waste #3.

14.5 Expired primary and working PCB standards. This waste is placed in a waste container identified as "PCB Standard Waste", Waste #8.

14.6 Samples containing polychlorinated biphenyls (PCB's) at concentrations ≥50 ppm are regulated under the Toxic Substance Control Act (TSCA) and must be segregated from all other waste streams. Analysts are responsible for contacting the Group Leader, Sample Control, and the Health and Safety Coordinator immediately if a sample falls into the TSCA category.

Carrier Gas:	Hydrogen or Helium
Make-up Gas:	Nitrogen

Table 3							
Calibration Levels ng/mL							
	Level 1	Level 2	Level 3	Level 4	Level 5	Level 6	Level 7[1]
AR1660	10	100	250	500	1000	2000	4000
AR1242[2]				500			
AR2154[2]				500			
AR1232[2]				500			
AR1248[2]				500			
Surrogates are included with all the calibration mixes at the following levels:							
TCMX	0.5	5	12.5	25	50	100	200
DCB	0.5	5	12.5	25	50	100	200

[1] Level 7 is optional and should only be used if linearity can be maintained on the instrument to this level.

[2] Aroclors may be quantitated within the range 100 to 2000 ng/mL (4000 ng/mL if the level 7 1016/1260 standard is included). If the Aroclor is more concentrated, it must be reanalyzed at a dilution.

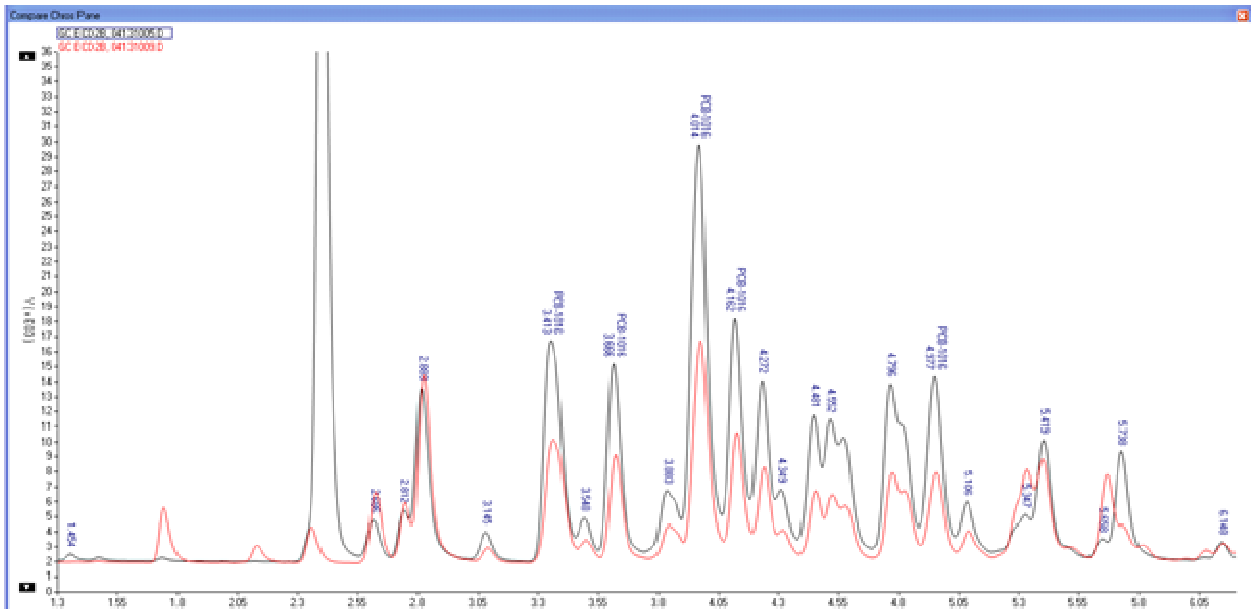
Table 4			
LCS/Matrix Spike and Surrogate Spike Levels for Aroclor Analysis µg/L, µg/wipe or µg/kg			
	Aqueous/Wipe	Soil/Tissue	Waste
Aroclor 1016/1260	10	333	10,000
TCMX (surrogate)	0.20	6.67	200
DCB (surrogate)	0.20	6.67	200

Table 5					
Preparation of Calibration Standards					
Calibration Level	1016/1260 Intermediate (µL)	1221 + 1254 Stock (µL)	1232 Stock (µL)	1242 Stock (µL)	1248 Stock (µL)
Level 1	4				
Level 2	20				
Level 3	80				
Level 4	1000	250	250	250	250
Level 5	400				
Level 6	800				
Level 7	1600				

The surrogate stock is purchased (Decachlorobiphenyl and Tetrachloro-m-xylene) at 200 ug/mL.

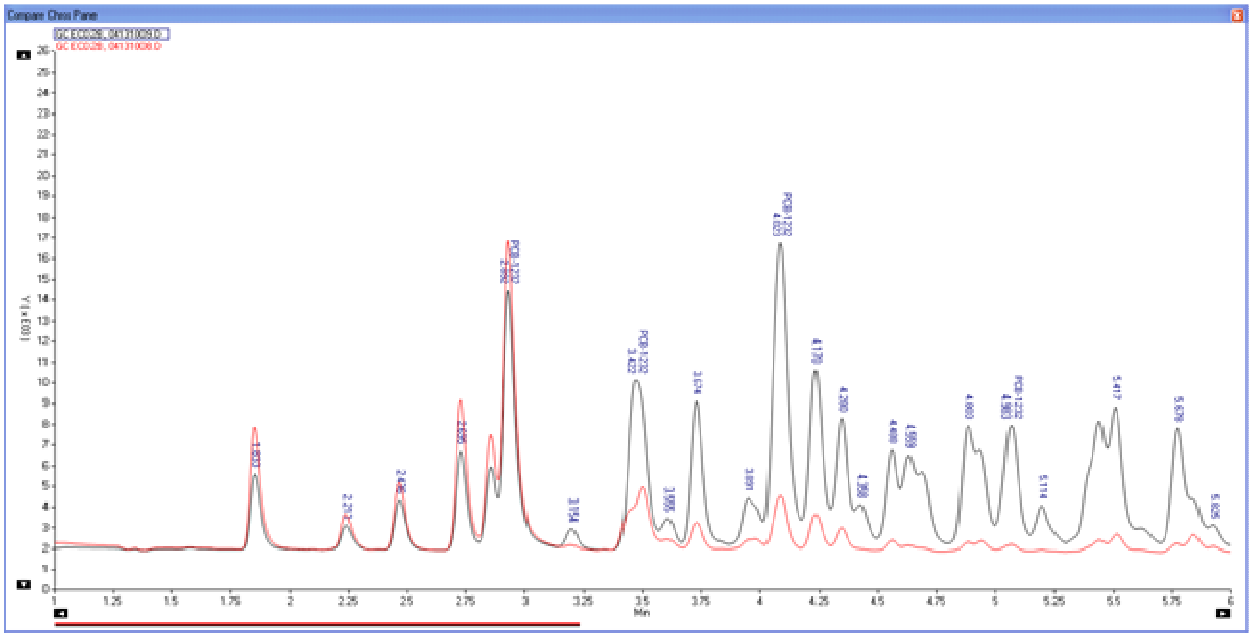
The Aroclor 1016 and 1260 stock standards are purchased as certified standards in isooctane at 1000 ug/mL. The other five Aroclor stock standards are purchased at 200 ug/mL.

For Aroclors 1016 and 1260, an intermediate standard is prepared by diluting 1.0 mL of each of the stock standards and 0.25 mL of the surrogate stock standard to 10.0 mL in hexane. The intermediate Aroclor 1016/1260 standard concentrations are 100 ug/mL for each Aroclor and 5 ug/mL for each surrogate.



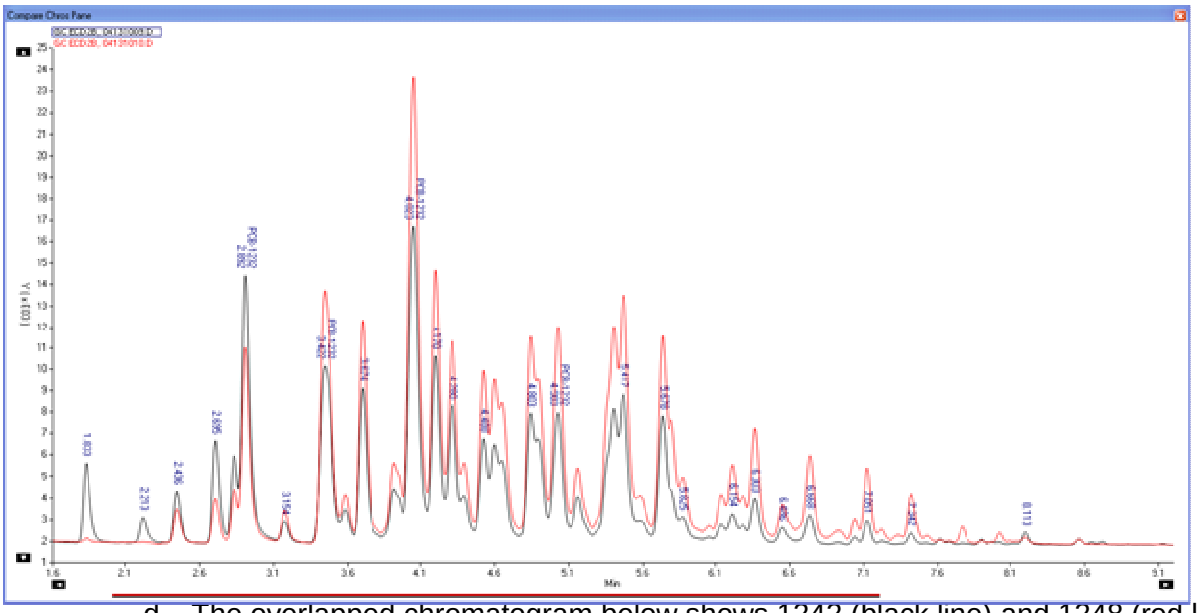
The Aroclor 1016/1260 calibration standards are prepared by diluting the volumes noted in Table C-6 to a 40.0 mL final volume in hexane except for the Level 3 standard, which is taken to a 200mL final volume in hexane.

The mid-level (Level 3) calibration standards for each of the other five Aroclors (1221, 1232, 1242, 1248, 1254) are prepared by diluting 0.25 mL of the appropriate stock standard to a final volume of 100 mL in hexane. Aroclors 1221 and 1254 are combined into one standard and Aroclors 1232, 1242, and 1248 are prepared individually.

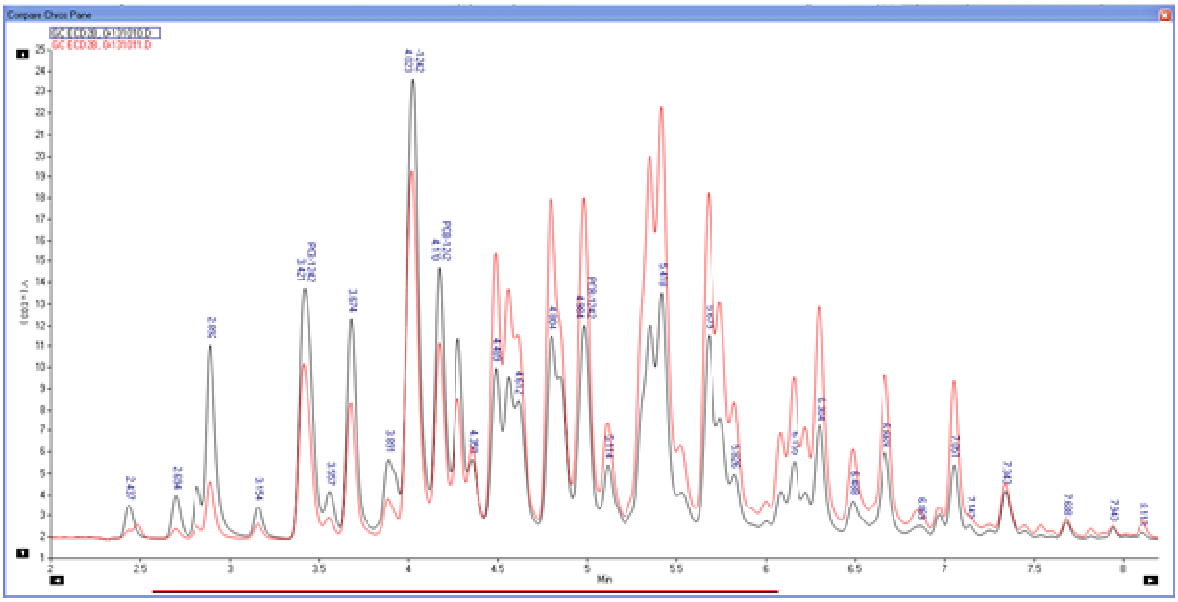


Appendix A

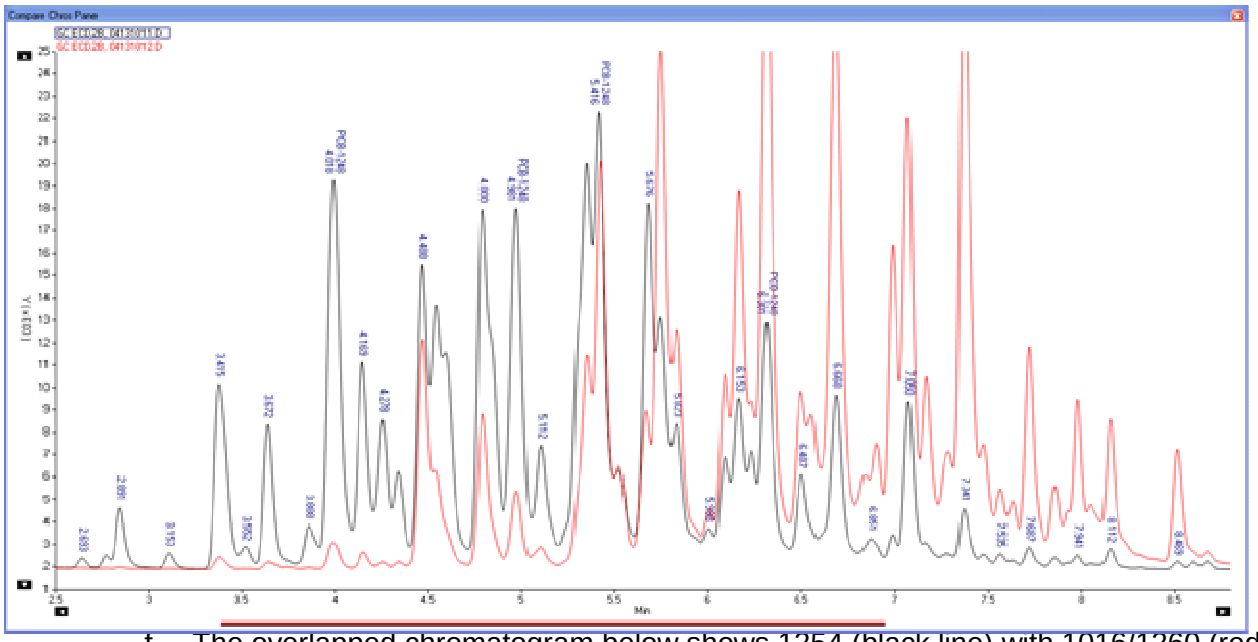
Aroclor Identification



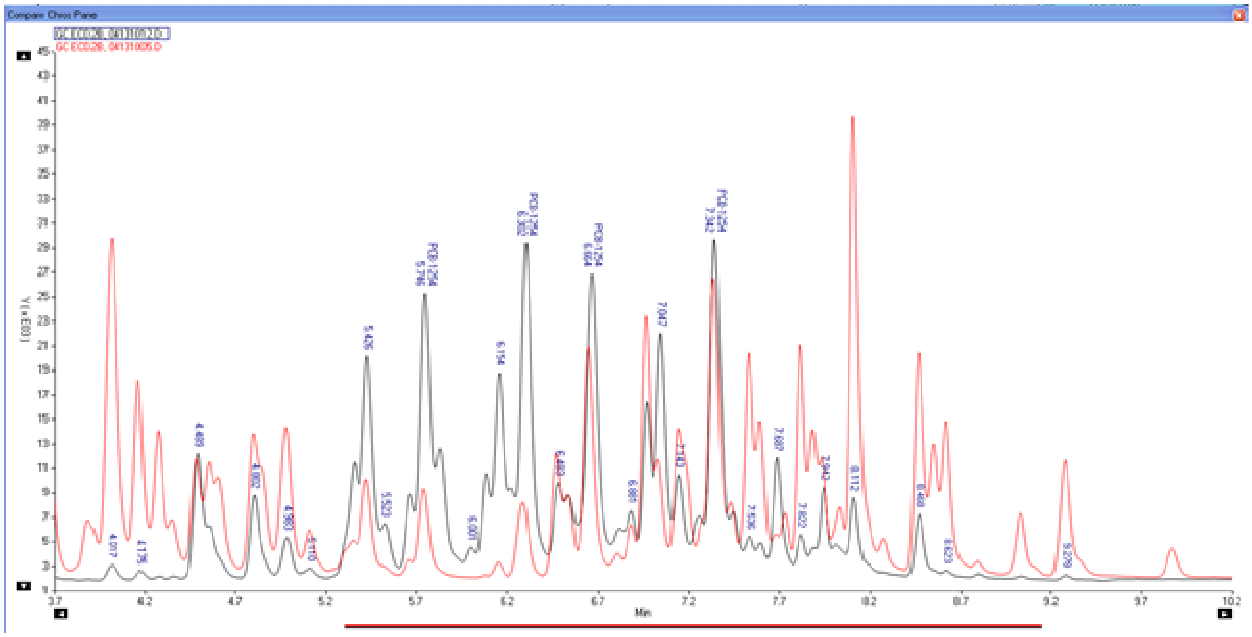
1. Aroclors are mixtures of individual PCBs, which is why multiple peaks are present for each Aroclor standard. The different Aroclors can contain the same peaks, therefore a specific set of peaks, as well as the pattern of the peaks are used for identification. The percentage of each PCB in the Aroclor mix will also be different between Aroclors, therefore the ratio of the peak heights/areas will be different.
2. Within the 12xx designated Aroclors, the higher the number, the more chlorines are part of the compounds that comprise the Aroclor, therefore the molecular weights are higher, and the later the peaks of the mix elute.
3. When choosing the five (or three for 1221) peaks to be used for identifying and quantitating each Aroclor, choose prominent peaks from across the pattern. The previous standard patterns should be followed, and an experienced analyst should be consulted before changing the peaks used.
4. Standards of the separate individual Aroclors are injected periodically to verify the peak retention times and patterns.
5. Below are some examples of peaks/patterns for Aroclors:
    a. The overlapped chromatogram below shows a mixture of 1016 and 1260 (black line) with 1232 (red line). The large peak around 2.35 minutes is TCMX surrogate. 1016 and 1260 patterns are completely separate. 1016 and 1232 have similar patterns, however the very early peaks that appear in 1232 are not present in 1016, and the front end of the pattern is stronger (higher peaks) where 1016 is stronger on the back end of the pattern.



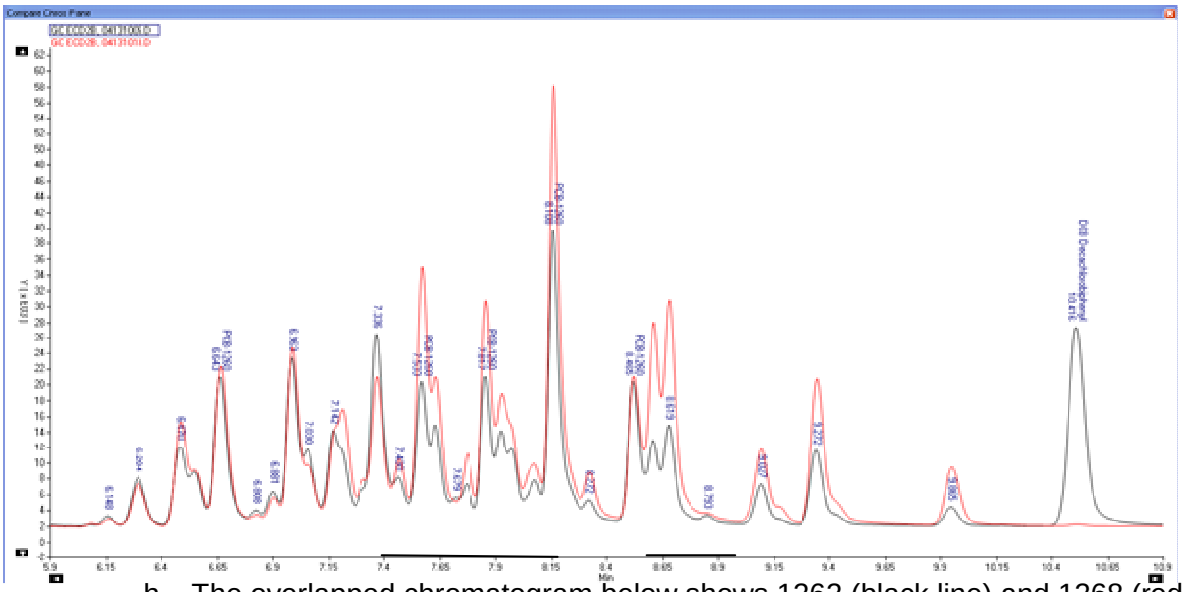
b. The overlapped chromatogram below shows a mixture of 1232 (black line) and 1221 (red line). The front end of the patterns are identical, but 1232 has later peaks that are not present in 1221.



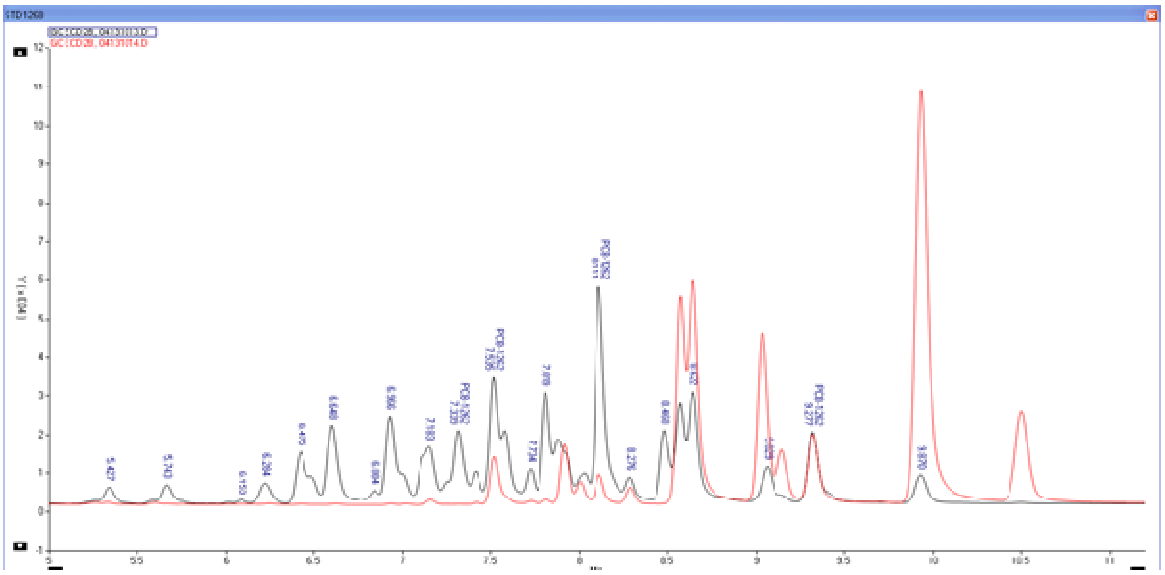
c. The overlapped chromatogram below shows 1232 (black line) and 1242 (red line). The very early peaks that appear in 1232 are not present in 1242, also the later eluting peaks of 1242 are stronger.



d. The overlapped chromatogram below shows 1242 (black line) and 1248 (red line). These Aroclors share all of the same peaks, so the relative strengths of the front and back of the pattern is the only way to distinguish the two. If this pattern is present, consult historical project data and an experienced analyst for the identification. Aroclors 1242 and 1248 are never reported together in a sample for this reason.

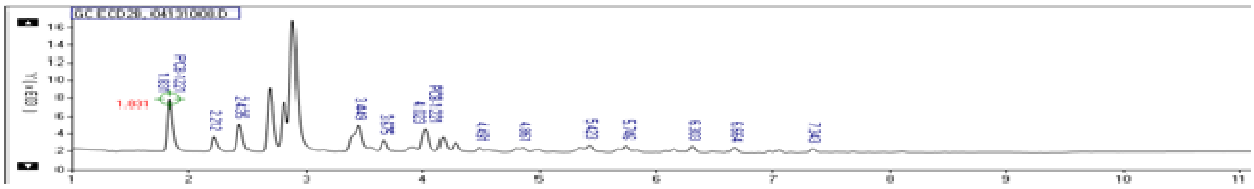


e. The overlapped chromatogram below shows 1248 (black line) and 1254 (red line), which are relatively easy to differentiate, as the front end of the pattern is much stronger in 1248.

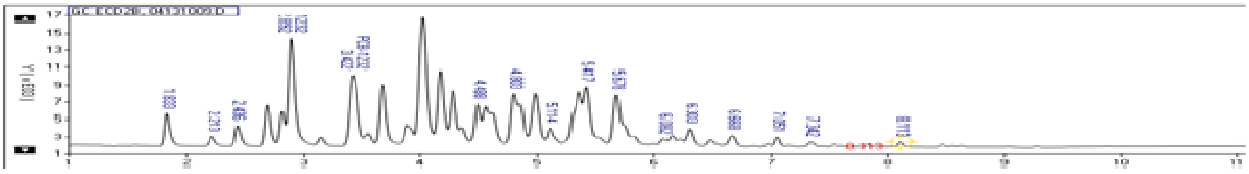


f. The overlapped chromatogram below shows 1254 (black line) with 1016/1260 (red line). While 1254 and 1260 share peaks, the relative strength of 1254 at the front end, and 1260 at the back end serve as the indicator between the two.

g. The overlapped chromatogram below shows 1260 (black line) and 1262 (red line). The ratio of the three peaks between 7-8 minutes and 8.4-8.7 minutes are the differences that indicate the identification for these Aroclors. For 1260, the first 3 show a slight decreasing pattern, and the second three a V shaped pattern, while for 1262 the first three sets are more of an arched pattern and the second three show a pattern of increasing height.

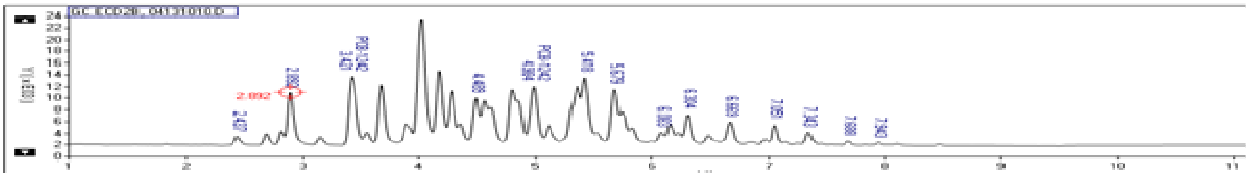


h. The overlapped chromatogram below shows 1262 (black line) and 1268 (red line). Clearly there are peaks present early in 1262 that are missing from 1268, and the back end of 1268 is much stronger.

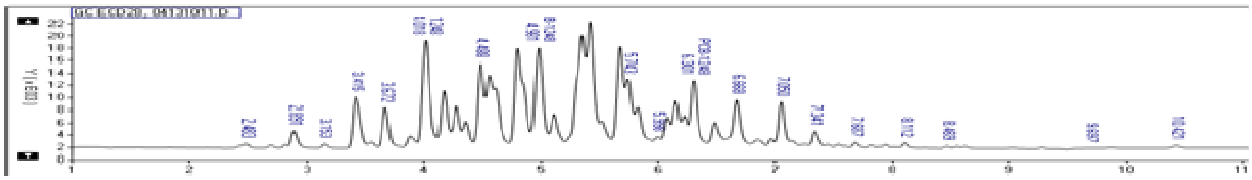


6. Example Individual Aroclor patterns:

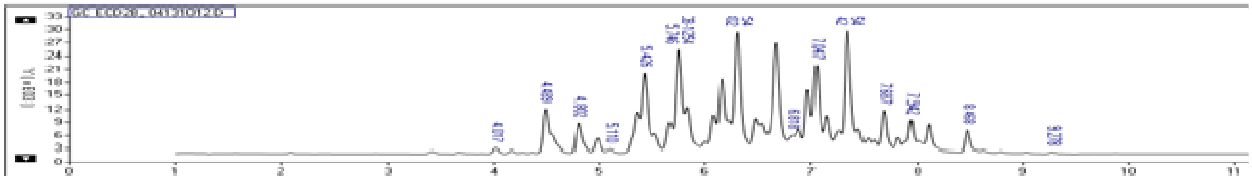
   a. Aroclor 1221



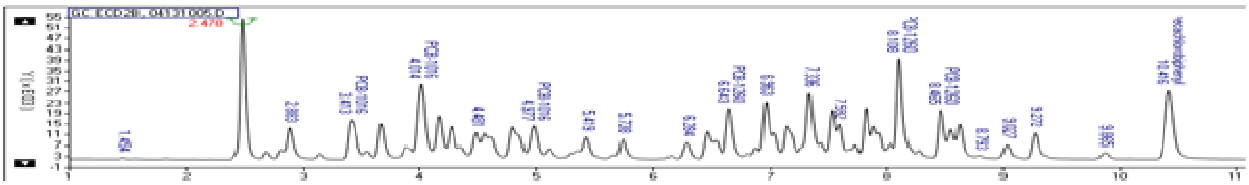
b. Aroclor 1232



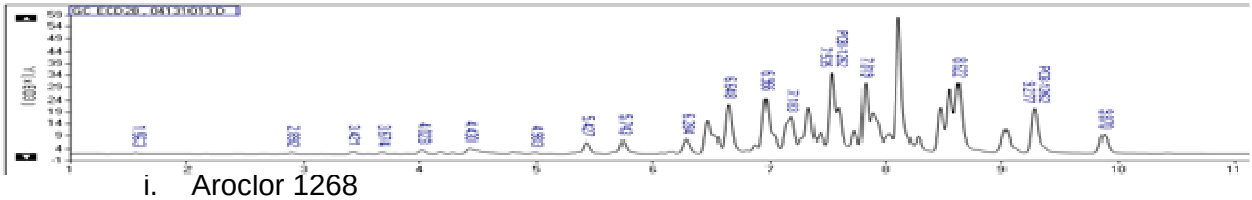
c. Aroclor 1016



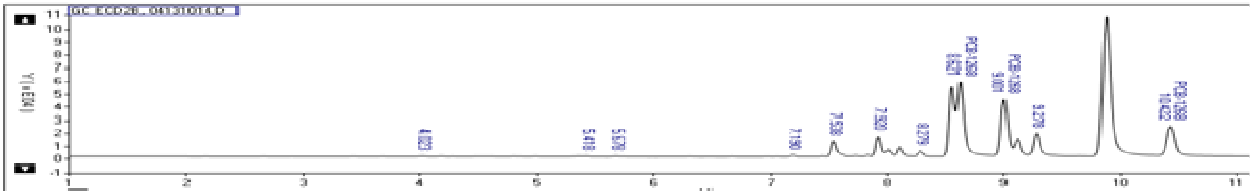
d. Aroclor 1242



e. Aroclor 1248



f. Aroclor 1254



g. Aroclor 1260

h. Aroclor 1262

i. Aroclor 1268

j.

7. When a mixture of Aroclors is present in a sample, unless the pattern of each is very clearly evident, consult historical project data and an experienced analyst for identification for reporting. Note that Aroclors 1242 and 1248 are never reported together in a sample.

    a. When a mixture of overlapping Aroclors is present, and the predominant Aroclor only is reported, it must be accompanied by the following narrative statement: "The following sample(s) contained more than one Aroclor with insufficient separation to quantify individually. The PCBs present are quantitated as the predominant Aroclor for reporting."

8. Most PCBs that are present in the environment have been there for years are "weathered". The patterns in environmental samples may not match the patterns present in standards. The relative intensity of the peaks may be different, or 1 or 2 peaks of the chosen pattern may be missing. Identification of weathered Aroclors take experience with reviewing these chromatograms, so consult a more experienced analyst or the laboratory Technical Director for instructions.

    a. To aid in the identification, make sure that the extracts have had cleanup performed.

    b. Compare to recent individual Aroclor standards.

    c. When reporting weathered Aroclors, the following statement (or similar) must be included in the case narrative: "The following sample(s) appear(s) to containe PCBs, however, due to weathering or other environmental processes, the PCBs in the sample(s) do not closely match any of the laboratory's Aroclor standards used for instrument calibration. The sample(s) has(have) been quantified and reported as Aroclor <XXXX> (OR as a mixture of Aroclors XXXX and YYYY). Due to the poor match with the Aroclor standard(s), there is increased qualitative and quantitative uncertainty associated with the result(s)."

Appendix B

Analysis of PCB Congeners Based on Method 8082A

1.0 SCOPE OF METHOD

1.1 This SOP Appendix describes procedures to be used when SW-846 Method 8000B is applied to the analysis of polychlorinated biphenyls (PCB) congeners by GC/ECD. This Appendix is to be applied when SW-846 Method 8082A is requested, and is applicable to extracts derived from any matrix, which are prepared according to the appropriate TestAmerica sample extraction SOP (PT-OP-001 or PT-OP-026). The PCBs are determined and quantitated as individual PCB congeners.

1.2 Table A-1 lists the congeners, which are routinely determined by this method and gives the Reporting Limits (RL) for each matrix. RLs given are based on the low level standard and the sample preparation concentration factors. Matrix interferences may result in higher RLs than those listed.

2.0 SUMMARY OF METHOD

2.1 This method presents conditions for the analysis of prepared extracts for PCB congeners. The PCBs are injected onto the GC column(s) and separated and detected by electron capture detection. Quantitation is by the external standard method.

3.0 DEFINITIONS

3.1 Refer to Section 3 of the main body of this SOP for definitions.

4.0 INTERFERENCES

4.1 Refer to Section 4 of the main body of this SOP for information regarding chromatographic interferences.

5.0 SAFETY

5.1 Refer to Section 5 of the main body of this SOP for general safety requirements.

5.2 PCB congeners have been classified as a potential carcinogen under OSHA. Concentrated solutions of PCB congeners must be handled with extreme care to avoid excess exposure. Contaminated gloves and clothing must be removed immediately. Contaminated skin surfaces must be washed thoroughly.

6.0 EQUIPMENT AND SUPPLIES

6.1 Refer to Section 6 of the main body of this SOP for equipment and supplies.

6.2 Refer to Table B-2 for analytical column requirements

7.0 REAGENTS AND STANDARDS

7.1 Reagents

7.1.1 Acetone, 99.4% for organic residue analysis.

7.1.2 Hexane, pesticide grade.

7.1.3 Carrier Gas: ≥ 99.99999% pure hydrogen.

7.1.4 Make-up Gas: ≥ 99.99980% pure nitrogen.

7.2 Standards

7.2.1 Stock Standards

7.2.1.1 All standards must be refrigerated at >0.0˚C but ≤6.0℃. All stock standards must be protected from light. Stock standard solutions should be brought to room temperature before use.

7.2.1.2 Stock standards are monitored for signs of degradation or evaporation. The standards must be replaced annually or earlier if the vendor indicates an earlier date.

7.2.1.3 Dilutions from stock standards cannot have a later expiration date than the date assigned to the parent stock solutions. The standards must be replaced at least every six months, or sooner, if comparison with check standards indicates a problem.

7.2.2 PCB Congener and Surrogate Stock Standards

7.2.2.1 PCB Congener Stock Mix 1: For the PCB Congeners listed in Table B-1, except BZ-205 (surrogate), a commercially prepared stock standard solution is obtained. The concentration of the PCB Congeners contained in Mix 1 is 4.0 ug/mL and the concentration of the TCMX (surrogate) is 6.6 ug/mL PCB Congener Stock Add-on Mix: This stock standard is prepared by adding 400 uL of 100 ug/mL of the following individual congener standards brought to a final volume of 10 mL with Hexane and resulting in a final concentration of 4 ug/mL: BZ-205 (surrogate).

7.2.2.2 TCMX (2000 ug/mL) and BZ-205 (100 ug/mL) Surrogate Stock Standards are commercially purchased standards.

7.2.2.3 PCB Congener Matrix Spike Stock Standard is a commercially purchased standard containing BZ-8, BZ-18, BZ-28, BZ-44, BZ-52, BZ-66, BZ-77, BZ-101, BZ-105, BZ-118, BZ-126, BZ-128, BZ-138, BZ-153, BZ-170, BZ-180, BZ-187, BZ-195 and BZ-206 at a concentration of 100 ug/mL. (NOTE: BZ-49, BZ-81, BZ-87, BZ-114, BZ-123, BZ-156, BZ-157, BZ-167, BZ-169, BZ-187 and BZ-189 are also used as needed, however these are separate commercially purchased stock solutions also at a concentration of 100 ug/mL).

7.2.3 Calibration Curve Standard Solutions

The calibration standards are prepared as follows:

Calibration Level	Recipe	Stock Concentration (ug/mL)	Final Volume (ml of Hexane)
1	5 uL of PCB Congener Stock Mix 1 and 5 uL of PCB Congener Stock Add-on Mix	4 ug/mL (TCMX 6.6 ug/mL)	40
2	10 uL of PCB Congener Stock Mix 1 and 10 uL of PCB Congener Stock Add-on Mix	4 ug/mL (TCMX 6.6 ug/mL)	40
3	25 uL of PCB Congener Stock Mix 1 and 25 uL of PCB Congener Stock Add-on Mix	4 ug/mL (TCMX 6.6 ug/mL)	40
4	50 uL of PCB Congener Stock Mix 1 and 50 uL of PCB Congener Stock Add-on Mix	4 ug/mL (TCMX 6.6 ug/mL)	40
5	100 uL of PCB Congener Stock Mix 1 and 100 uL of PCB Congener Stock Add-on Mix	4 ug/mL (TCMX 6.6 ug/mL)	40
6	200 uL of PCB Congener Stock Mix 1 and 200 uL of PCB Congener Stock Add-on Mix	4 ug/mL (TCMX 6.6 ug/mL)	40

7.2.3.1 Refer to Table B-3 for details of calibration standard concentrations.

7.2.4 Surrogate Standards

7.2.4.1 The Working Surrogate Solution is made as follows: 2.5 uL of the 2000 ug/mL commercially purchased TCMX stock and 50 uL of the 100 ug/mL commercially purchased BZ-205 stock brought to a final volume of 20 mL with Acetone (see section 7.2.2.3). The final concentration of the Working Surrogate Solution is 0.025 ug/mL. Refer to Table A-3 for details of surrogate standard concentrations in the calibration standards.

NOTE: The Working Surrogate Solution is prepared and used as part of the scope of the organic preparation SOP PT-OP-001 and PT-OP-026. The preceding information is provided for reference only.

7.2.5 Laboratory Control Standard (LCS) and Matrix Spiking (MS) Solution

The working LCS/MS spiking solution is prepared by combining 1mL of the PCB Congener Matrix Spike Stock Standard and 1 mL each, as needed, of the BZ-49, BZ-81, BZ-87, BZ-114, BZ-123, BZ-156, BZ-157, BZ-167, BZ-169, BZ-187 and BZ-189 stock standards brought to a 100 mL final volume with Acetone. The final concentration of the working LCS/MS spiking solution is 1.0 ug/mL.

NOTE: The LCS/MS spiking solution is prepared and used as part of the scope of the organic preparation SOP SOP PT-OP-001 and PT-OP-026.

8.0 SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1 Refer to Section 8 of the main body of this SOP.

9.0 QUALITY CONTROL

9.1 Refer to Section 9 of the main body of this SOP.

10.0 PROCEDURE

10.1 Calibration and Standardization

10.1.1 PCB Congeners uses an External Standard Calibration as follows:

External standard calibration involves the comparison of instrument responses from the samples to the responses from the target compounds in the calibration standards. The area (or height) of a peak in a sample chromatogram is compared to the area (or height) of the peak in the standard chromatograms that appears at the same retention time. The ratio of the detector response to the concentration of the target analyte in the calibration standard is defined as the calibration factor (CF) and is calculated as follows:

$$CF = \frac{Area\ or\ Height\ of\ Peak}{Mass\ Injected}$$

Note: It is also possible to use the concentration of the standard rather than the mass injected.

10.1.2 Refer to Section 10 of the main body of this SOP for the other general calibration requirements.

10.2 Initial Calibration

10.2.1 Refer to Table B-5 for the initial calibration analytical sequence.

10.2.2 The response for each PCB congener will be calculated by the procedures described in the general method for 8082A analysis, with the following modifications.

- A minimum five-point calibration of each of the individual congeners mixes is generated. At least 2 separate mixes are prepared to ensure that there is complete resolution of all congeners in the mixes. Calibration levels are listed in Table B-3.

10.3 Initial Calibration Verification

10.3.1 The ICV will consist of second source standards of all congeners of interest. The ICV is prepared from a second source stock standard of a concentration of 4ppm for all congeners of interest. 25 uL of the ICV stock standard is added to Hexane and brought to a final volume of 40 mL for a concentration of 0.0025 ppm.

10.3.2 Refer to section 9.9.4 in the main body of this SOP for acceptance criteria and corrective actions for failures.

10.3.3 12 hour Calibration

The 12-hour calibration verification must be analyzed within 12 hours of the start of the initial calibration and at least once every 12 hours thereafter if

samples are being analyzed. If there is a break in the analytical sequence of greater than 12 hours, then a new continuing calibration run must be analyzed before proceeding with the sequence. If more than 12 hours have elapsed since the injection of the last sample in the analytical sequence, a new analytical sequence must be started with a 12-hour calibration.

The retention time windows for any analytes included in the daily calibration are updated.

For this method, samples must be <u>bracketed</u> with successful calibration verification runs.

10.3.4 Calibration Verification

10.3.4.1 A mid-level calibration mix is analyzed as the calibration verification standard. This is analyzed after every 20 samples or 12 hours, including matrix spikes, LCS, and method blanks. (Depending on the type of samples, it may be advisable to analyze verifications more frequently in order to minimize reruns.).

10.3.4.2 The daily CCV analysis at a concentration other than the mid-level (to meet NELAC requirements) will consist of all of the congeners of interest. All other CCVs will be mid-level calibration standards.

10.3.5 Procedure - Refer to Section 10 of the main body of this SOP for general procedural requirements.

10.3.6 Suggested gas chromatographic conditions are given in Table B-2.

10.3.7 The suggested analytical sequence is given in Table B-5.

11.0 CALCULATIONS / DATA REDUCTION

11.1 Identification of Congeners

Retention time windows are used for identification of PCB congeners. Second column confirmation must be performed.

11.2 Refer to section 11 of the main body of this SOP for calculation details.

12.0 METHOD PERFORMANCE

12.1 Refer to section 12.3 for initial demonstration of capability requirements under Section 12 of the main body of this SOP. The LCS spiking level is used for IDOC.

13.0 POLLUTION CONTROL

13.1 Refer to Section 13 of the main body of this SOP.

14.0 WASTE MANAGEMENT

14.1 Refer to Section 14 of the main body of this SOP.

15.0 REFERENCES

15.1 Refer to Section 15 of the main body of this SOP.

16.0 METHOD MODIFICATIONS

16.1 Refer to Section 16 of the main body of this SOP.

17.0 ATTACHMENTS

17.1 Table B-1: Standard Analyte List and Reporting Limits

[1]Individual Congeners are spiked as needed.

Table B-5		
Suggested Analytical Sequence		
Initial Calibration		
Injection #		
Solvent blank (optional)		
PCB Congener Mix 1	5-point	6-point
ICV (second source standard(s) of all congeners of interest)		
Samples 1-20 (or 12 hours, whichever is more frequent)		
Solvent blank (optional)		
PCB Congener Mix 1		Level 3
After 12 hours:		
PCB Congener Mix 1		Level 3
Samples 1-20 (or 12 hours)		
Solvent blank (optional)		
PCB Congener Mix 1		Level 3
12 hour Calibration		

At least every 24 hours, counting from the start of the initial calibration, or from the start of the last daily calibration, the retention time windows must be updated.

Title: Determination of Inorganic Anions by Ion Chromatography

Method(s): EPA Method 300.0 and SW846 Method 9056A

Approvals (Signature/Date):

1. SCOPE AND APPLICATION

1.1. This method covers the determination of fluoride, chloride, nitrite-nitrogen, bromide, nitrate-nitrogen, ortho-phosphate and sulfate in drinking water, surface water, mixed domestic and industrial wastewaters, groundwater, reagent waters, solids (after extraction 10.1.2) and leachates (when no acetic acid is used).

1.2. On occasion clients may request slight modifications to this SOP. Any modification to this procedure must be approved by the QA department of the Laboratory or Technical Director, and documented fully in an NCM.

1.3. The reporting limits for each anion are listed below. Limits for soil are based on an extraction of 1 unit of soil / 10 of water.

Analyte	Water RL (mg/L)	Soil RL (mg/Kg)
Bromide	0.10	2.0
Chloride	1.0	10.0
Fluoride	0.10	1.0
Nitrate-N	0.10	0.50
Nitrite-N	0.05	0.50
Ortho-Phosphorous	0.50	5.0
Sulfate	1.0	10.0

2. SUMMARY OF METHOD

2.1. A 10uL (INTEGRION, 2100A and 2100B) or 50uL (IC2000) volume of sample is introduced into the ion chromatograph. The sample is pumped through three different ion exchange columns and into a conductivity detector. The first two columns, a pre-column or guard column and a separator column, are packed with low-capacity, strongly basic anion exchange resin. Ions are separated into discrete bands based on their affinity for the exchange sites of the resin. The last column is a suppresser column that reduces the background conductivity of the eluent to a low or negligible level and converts the anions in the sample to their corresponding acids. The separated anions in their acid form are measured using an electrical conductivity cell. Anions are identified based on their retention times compared to known standards. Quantitation is accomplished by measuring the peak height or area and comparing it to a linear calibration curve generated from known standards.

3. DEFINITIONS

3.1. TALS – Eurofins TestAmerica Laboratory Information Management System

3.2. NCM - Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3. Refer to the glossary in the Pittsburgh Laboratory Quality Manual (PT-QA-M-001) for additional definitions.

4. INTERFERENCES

4.1. Interferences can be caused by substances with retention times that are similar to and overlap those of the anion of interest. Large amounts of an anion can interfere with the peak resolution of an adjacent anion. Sample dilution and/or fortification can be used to solve most interference problems associated with retention times.

4.2. The water dip or negative peak that elutes near, and can interfere with, the fluoride peak can usually be eliminated by the addition of concentrated eluent to each standard and sample. Due to the chromatographic conditions used, the addition of eluent to standards and samples is typically not necessary because the water dip is sufficiently resolved from the earliest eluting target anion (fluoride).

4.3. Method interferences may be caused by contaminants in the reagent water, reagents, glassware and other sample processing apparatus that lead to discrete artifacts or an elevated baseline in the ion chromatograms.

4.4. Any anion that is not retained by the column or only slightly retained will elute in the area of fluoride and interfere. Known co-elution is caused by carbonate and other small organic anions. At concentrations of fluoride above 1.5 mg/L, this interference may not be significant; however, it is the responsibility of the user to generate precision and accuracy information in each sample matrix.

4.5. The acetate anion elutes early during the chromatographic run. The retention times of the anions also seem to differ when large amounts of acetate are present. Therefore, this method is not recommended for leachates of solid samples when acetic acid is used for pH adjustment.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2. Specific Safety Concerns or Requirements

5.2.1. Exercise caution when using syringes with attached filter assemblies. Application of excessive force has, upon occasion, caused a filter disc to burst during the process.

5.3. Primary Materials Used

5.3.1. A complete list of materials used in the method can be found in the reagents and materials section. No chemicals used with this method pose any safety concerns.

5.4. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.5. Eye protection against splashing, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn when performing any task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated must be removed and properly discarded. Other types of contaminated gloves will be cleaned immediately.

5.6. Exposure to chemicals must be maintained as low as reasonably achievable, therefore; unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation when possible. Solvent and waste containers will be kept closed transfers are being made.

5.7. All work must be stopped in the event of a known or potential compromise to the health and safety of a Eurofins TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or the EH&S coordinator.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1. Instrumentation

6.1.1. Ion Chromatograph -- Analytical system complete with injector/autosampler, analytical columns, detectors and all necessary accessories.

Anion guard column: A protector of the separator column, usually packed with same substrate as the separator column. If the guard column is omitted from the system the retention times will be shorter.

- For INTEGRION, IC2100A & B - 2 x 50 mm, Dionex IonPac AG18, P/N 060555
- For IC2000 – 4 x 50 mm, Dionex IonPac AG22, P/N 064139

Anion separator column:

- For INTEGRION, IC2100A & B - 2 x 250mm, Dionex IonPac AS18, P/N 060553
- For IC2000 – 4 x 250mm, Dionex IonPac AS22, P/N 064141

Anion suppresser device: Dionex AERS 500 Carbonate Electrolytically Regenerated Suppressor, 2mm for IC2100A & B (P/N 085028), 4mm for IC2000 (P/N 085029). This suppressor eliminates the need for a regeneration solution.

Detector -- Conductivity cell: approximately 1.25 uL internal volume

Dionex –Chromeleon Data Chromatography Software

CHROM data processing software is used for data reporting

6.1.2. Eurofins TestAmerica Pittsburgh currently has three Dionex Ion Chromatographs

Models ICS2000 (IC2000), ICS2100 (2100A and 2100B) and Dionex Integrion HPIC (INTEGRION) all have an eluent generator, which allows facilitation of isocratic or gradient elution via the instrumentation's software program. This eluent gradiation may be performed to improve the chromatography of the instrument and to reduce the analysis runtime.

Note: At this time, IC2000 is using manually prepared eluent with an isocratic program.

6.1.3. Refer to PT-QA-022, Equipment Maintenance SOP, for routine instrument maintenance procedures.

6.2. Supplies

6.2.1. Analytical Balance capable of accurately weighing to the nearest 0.0001 g

6.2.2. Volumetric flasks, Class A, various sizes

6.2.3. Fixed or variable volume pipettors, calibration verified quarterly

7. REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements of this SOP can be met.

Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.1. Reagent water: Distilled or deionized water, free of the anions of interest. Water should contain particles no larger than 0.20 microns.

7.2. For the IC2000, prepare a 100x concentrated eluent solution by dissolving 8.40g of sodium bicarbonate ($NaHCO_3$) and 37.10g sodium carbonate (Na_2CO_3) in reagent water and dilute to 1000mL. Dilute 10.0mL of this concentrated solution to 1000 mL with reagent water to make the 1.0mM sodium bicarbonate/3.5mM sodium carbonate working eluent. The 100x concentrated eluent may also be purchased.

7.3. Dionex EGC III KOH Eluent Generator Cartridge, purchased from Thermo Scientific or equivalent vendor, is used by INTEGRION, IC2100A and IC2100B.

7.4. All stocks are purchased from commercial sources. Primary and secondary sources are required for each target analyte.

7.4.1. Primary Commercial IC solution A (CCV/LCS): F^- - 125 mg/L, Cl^- - 2500 mg/L, Br^- - 500 mg/L, NO_3^- - N- 125 mg/L, PO_4^{-3} – P - 125 mg/L, SO_4^{-2} - 2500 mg/L

7.4.2. Primary Commercial IC solution B (CCV/LCS): NO_2^- - N- 125 mg/L

7.4.3. Secondary Commercial stock solution A (ICV): F^- - 25 mg/L, Cl^- - 500 mg/L, Br^- - 100 mg/L, NO_3^- - N- 25 mg/L, PO_4^{-3} – P - 25 mg/L, SO_4^{-2} - 500 mg/L

7.4.4. Secondary Commercial stock solution B (ICV): NO_2^- - N- 25 mg/L

7.5. Working standards: Prepare calibration standards fresh daily in reagent grade water. Final concentrations of working standards are shown below:

NOTE: The following standard preparation tables are for example purposes and equivalent preparation volumes may be used.

Calibration Standard #1: take 0.05 mL of calibration STD #6 and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	0.025 mg/L
Chloride	0.50 mg/L
Nitrite	0.025 mg/L
Bromide	0.100 mg/L
Nitrate	0.025 mg/L
Ortho-Phosphate	0.025 mg/L
Sulfate	0.50 mg/L

Calibration Standard #2: take 0.1 mL of calibration STD #6 and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	0.050 mg/L
Chloride	1.00 mg/L
Nitrite	0.050 mg/L
Bromide	0.200 mg/L
Nitrate	0.050 mg/L
Ortho-Phosphate	0.050 mg/L
Sulfate	1.00 mg/L

Calibration Standard #3: take 0.5 mL of calibration STD #6 and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	0.250 mg/L
Chloride	5.00 mg/L
Nitrite	0.250 mg/L
Bromide	1.00 mg/L
Nitrate	0.250 mg/L
Ortho-Phosphate	0.250 mg/L
Sulfate	5.00 mg/L

Calibration Standard #4: take 0.5 mL of calibration STD #8 and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	0.500 mg/L
Chloride	10.00 mg/L
Nitrite	0.500 mg/L
Bromide	2.00 mg/L
Nitrate	0.500 mg/L
Ortho-Phosphate	0.500 mg/L
Sulfate	10.00 mg/L

Calibration Standard #5: take 1.0 mL of calibration STD #8 and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	1.00 mg/L
Chloride	20.00 mg/L
Nitrite	1.00 mg/L
Bromide	4.00 mg/L
Nitrate	1.00 mg/L
Ortho-Phosphate	1.00 mg/L
Sulfate	20.00 mg/L

Calibration Standard #6: take 0.1 mL of Primary solution A (7.4.1) and 0.1 mL of Primary solution B (7.4.2) and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	2.50 mg/L
Chloride	50.00 mg/L
Nitrite	2.50 mg/L
Bromide	10.00 mg/L
Nitrate	2.50 mg/L
Ortho-phosphate	2.50 mg/L
Sulfate	50.00 mg/L

Calibration Standard #7 for IC2000: take 0.15 mL of Primary solution A (7.4.1) and 0.15 mL of Primary solution B (7.4.2) and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	3.75 mg/L
Chloride	75.00 mg/L
Nitrite	3.75 mg/L
Bromide	15.00 mg/L
Nitrate	3.75 mg/L
Ortho-phosphate	3.75 mg/L
Sulfate	75.00 mg/L

Calibration Standard #8 for INTEGRION, IC2100A&B (Standard #8 for IC2000): take 0.2 mL of Primary solution A (7.4.1) and 0.2 mL of Primary solution B (7.4.2) and dilute to 5.0 mL final volume.

Analyte	Final Conc.
Fluoride	5.00 mg/L
Chloride	100.00 mg/L
Nitrite	5.00 mg/L
Bromide	20.00 mg/L
Nitrate	5.00 mg/L
Ortho-phosphate	5.00 mg/L
Sulfate	100.00 mg/L

Calibration Standard #9 for INTEGRION, IC2100A&B: take 0.6 mL of Primary solution A (7.4.1) and 0.6 mL of Primary solution B (7.4.2) and dilute to 10.0 mL final volume.

Analyte	Final Conc.
Fluoride	7.50 mg/L
Chloride	150.0 mg/L
Nitrite	7.50 mg/L
Bromide	30.0 mg/L
Nitrate	7.50 mg/L
Ortho-phosphate	7.50 mg/L
Sulfate	150.0 mg/L

Calibration Standard #10 for INTEGRION, IC2100A&B only: take 0.8 mL of Primary solution A (7.4.1) and 0.8 mL of Primary solution B (7.4.2) and dilute to 10.0 mL final volume.

Analyte	Final Conc.
Fluoride	10.0 mg/L
Chloride	200.0 mg/L
Bromide	40.0 mg/L
Nitrate	10.0 mg/L
Ortho-phosphate	10.0 mg/L
Sulfate	200.0 mg/L

NOTE: Standard 10 may not be used for Fluoride or Nitrite

7.5.1. **Continuing Calibration Verification**

Dilute 0.30mL of primary stock standards 7.4.1 and 7.4.2 to 15mL to prepare the CCV solution with the concentrations listed below. Prepare fresh daily.

CCV Solution Concentrations

Analyte	Final Conc.
Fluoride	2.5 mg/L
Chloride	50.0 mg/L
Nitrite	2.5 mg/L
Bromide	10.0 mg/L
Nitrate	2.5 mg/L
Ortho Phosphate	2.5 mg/L
Sulfate	50.0 mg/L

7.5.2. **Laboratory Control Sample**

Dilute 0.50mL of secondary stock standards 7.4.3 and 7.4.4 to 10.0mL to prepare the LCS solution with the concentrations listed below for IC2100A and IC2100B. For IC2000, LCS concentrations are twice as high, prepared by

diluting 1.0mL of the secondary stock standards to 10.0mL.. For soil sample batches, the LCS is taken through the leaching process along with the samples. Prepare LCS solution fresh daily.

LCS Solution Concentrations

Analyte	Final Conc. INTEGRION IC2100A & 2100B	Final Conc. IC2000
Fluoride	1.25 mg/L	2.50 mg/L
Chloride	25.0 mg/L	50.0 mg/L
Nitrite	1.25 mg/L	2.50 mg/L
Bromide	5.0 mg/L	10.0 mg/L
Nitrate	1.25 mg/L	2.50 mg/L
Ortho Phosphate	1.25 mg/L	2.50 mg/L
Sulfate	25.0 mg/L	50.0 mg/L

7.5.3. Matrix Spike Solution: Add 0.150 mL of primary stocks (7.4.1, and 7.4.2) dilute to 15 mL with sample for IC2100A and IC2100B. For IC2000, add 0.30mL of primary stocks to 15mL of sample. Final spike concentrations are the same as for the LCS listed in the table above.

7.5.4. Using the secondary stock standard(s) described in Section 7.4.3 and 7.4.4. Dilute these stock standards to as indicated in the table below to prepare the mixture to be used for the ICV solution. Prepare fresh daily.

ICV Solution:

Analyte	ml of Stock	Stock source	Final Vol.	Final Conc. mg/L
Fluoride	0.6 mL	7.4.3	5 mL	3.0
Chloride	0.6 mL	7.4.3	5 mL	60
Nitrite	0.6 mL	7.4.4	5 mL	3.0
Bromide	0.6 mL	7.4.3	5 mL	12
Nitrate	0.6 mL	7.4.3	5 mL	3.0
Ortho Phosphate	0.6 mL	7.4.3	5 mL	3.0
Sulfate	0.6 mL	7.4.3	5 mL	60

7.6.5 The ability to accurately detect concentrations at the reporting limit must be verified at a minimum with each calibration curve. The Reporting Limit Standard, (LLOQ, ICVL, or CCVL) is prepared by diluting 0.10mL of primary stock standards 7.4.1 and 7.4.2 to 250mL. The concentrations of this solution are listed below. Prepare fresh daily.

LLOQ/CCVL Solution Concentrations

Analyte	Final Conc.
Fluoride	0.05 mg/L
Chloride	1.00 mg/L
Nitrite	0.05 mg/L
Bromide	0.20 mg/L
Nitrate	0.05 mg/L
Ortho Phosphate	0.05 mg/L
Sulfate	1.00 mg/L

NOTE: All standards should be stored in the dark at > 0.0°C but ≤6.0 °C. Replace these standards when instrument response indicates target analyte degradation may have occurred or after the standard has expired, whichever occurs first. Stock standards are purchased from a vendor and have vendor assigned expiration dates. The dilutions made from the stocks are prepared weekly. Nitrite and ortho-phosphate are particularly light and oxygen sensitive and should be prepared daily if needed.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1. Samples should be collected in plastic bottles. All bottles must be thoroughly cleaned and rinsed with reagent water. The volume collected should be sufficient to ensure a representative sample, allow for replicate analysis, if required, and minimize waste disposal.

8.2. Sample preservation and holding times for the anions that can be determined by this method for water samples are as follows:

Method	Analyte	Preservation	Holding Time	Reference
300.0/9056A	Fluoride	>0.0°C but ≤6.0 °C	28 days	40CFR Part 136 Table II
300.0/9056A	Chloride	>0.0°C but ≤6.0 °C	28 days	40CFR Part 136 Table II
300.0/9056A	Nitrite	>0.0°C but ≤6.0 °C	48 hours	40CFR Part 136 Table II
300.0/9056A	Bromide	>0.0°C but ≤6.0 °C	28 days	40CFR Part 136 Table II
300.0/9056A	Nitrate	>0.0°C but ≤6.0 °C	48 hours	40CFR Part 136 Table II
300.0/9056A	Ortho-Phosphate	>0.0°C but ≤6.0 °C	48 hours; filter sample within 15 minutes of collection	40CFR Part 136 Table II
300.0/9056A	Sulfate	>0.0°C but ≤6.0 °C	28 days	40CFR Part 136 Table II

Note: Soil leachates (i.e DI Leach, ASTM Leach, SPLP, etc.) will follow the same holding times as the water samples; starting from the time of extraction. See Section 10.1.2 for the soil extraction procedure. If project specific requirements exist for sample handling, follow the project specific protocols.

9. QUALITY CONTROL

9.1. The following quality control samples are prepared and analyzed with each batch of 20 or fewer samples of the same matrix.

QC Samples	Frequency	Acceptance Criteria	Corrective Action
Method Blank (MB)	1 per batch of 20 samples per matrix	< MDL – Method 300.0 < RL – Method 9056A	Rerun once, reanalyze all samples since the last acceptable MB
Laboratory Control Sample (LCS)	1 per batch of 20 samples	90-110% - Method 300.0 80-120% - Method 9056A	Reanalyze all samples associated with unacceptable LCS
Matrix Spike Sample (MS/MSD)[1]	For Method 300.0: 1 MS/MSD pair per 10 samples For Method 9056A: 1 MS/MSD pair per batch or 20 samples	Meets laboratory limits Method 300.0: 90-110% ±20% RPD Method 9056A: 80-120% ±15% RPD	Supervisor's technical judgment

[1]The parent sample for MS/MSD is randomly selected, unless specifically requested by a client.

9.1.1. Method Blank (MB): One method blank must be processed with each batch of 20 or fewer samples of similar matrix. The method blank for aqueous samples consists of reagent grade water that is filtered along with the samples. The method blank is used to identify any system and process interferences or contamination of the analytical system that may lead to the reporting of elevated analyte concentrations or false positive data. Because there is no preparation step for aqueous samples, the method blank and CCBs are the same for this analysis. The method blank should not contain any analyte of interest above the MDL for method 300.0, or above the RL for method 9056A. All samples are associated with the immediately preceding MB/CCB.

NOTE: A solid matrix (simulated using glass or plastic beads or Teflon chips because purified sand still contains chloride contamination) will be prepared and tumbled with soils extracted using the 1-Hour DI Leaching procedure found in SOP PT-WC-033.

- If the MB contains any of the target anions above the MDL/RL, the source of the contamination should be investigated and corrected, and all associated samples reanalyzed, unless one of the following situations exists:
  - If the MB is contaminated, but associated samples results are >10x the MB concentration, results may be reported using the "Method Blank – Report, 10X" NCM.

- If the contamination anion is not detected above the MDL/RL in the associated samples, results may be reported with qualifier and using the "Method Blank – Report, ND" NCM.
- If neither of the above criteria are met, but a reanalysis will be outside the holding time, contact the Project Manager for approval from the client to perform the reanalysis.

9.1.2. Laboratory Control Sample (LCS): One LCS must be processed with each batch of 20 or fewer samples of similar matrix. The LCS is filtered along with samples. The LCS is used to monitor the accuracy of the analytical process. On-going monitoring of the LCS results provides evidence that the laboratory is performing the method within acceptable accuracy and precision guidelines. The LCS consists of reagent grade water* containing a known amount of target analytes. The LCS is prepared from the secondary stock standard used to prepare ICV. The LCS recovery must be within 90-110% of the true value for method 300.0 and 80-120% for method 9056A. Because the LCS is prepared from the primary source standard, has no additional prep procedures and must meet the same acceptance criteria, the LCS can serves as a CCV for method 300.0. For QC batch purposes all samples are associated with the immediately preceding LCS/CCV.

***NOTE**: A solid matrix (simulated using plastic beads or Teflon chips) LCS will be prepared with soils extracted using the 1-Hour DI Leaching procedure found in SOP PT-WC-033.

- If the LCS recovery falls outside the method acceptance limits, all associated samples must be reanalyzed with an acceptable LCS unless one of the following situations exists:
  - If the LCS fails with recovery above the upper control limit, and the associated sample result is non-detect, results may be reported with qualifier and the "LCS/LCSD - %R High" NCM.
  - If the reanalysis will be outside the holding time, contact the Project Manager for approval from the client to perform reanalysis.

9.1.3. Matrix Spike/Matrix Spike Duplicate (MS/MSD): For method 9056A, one MS/MSD pair must be processed for each batch of 20 or fewer samples of similar matrix. For method 300.0 an MS/MSD pair must be analyzed for every 10 samples analyzed. A matrix spike (MS) is a field sample to which a known concentration of target analyte has been added. A matrix spike duplicate (MSD) is a second aliquot of the same sample (spiked identically as the MS) prepared and analyzed along with the sample and matrix spike. Some client specific DQO's may require the use of sample duplicates in place of or in addition to MS/MSD's. The MS/MSD results are used to determine the effect of a matrix on the precision and accuracy of the analytical process. Due to the potential variability of the matrix of each sample, these results may have immediate bearing only on the specific sample spiked. Spiking levels should be similar to the concentrations expected in the samples, if known, otherwise, the MS/MSD shall be spiked the same as the LCS values.

- If the recovery of the MS or MSD is outside the limits, corrective action must be taken. Corrective action may include re-preparation and reanalysis of the parent sample and MS/MSD.
    - If the LCS recovery is within control limits, MS failure may be due to a matrix interference. Results may be reported with qualifier and the "MS/MSD- %R, LCS Pass" NCM.
    - If the MS/MSD recovery or RPD falls outside the acceptance range, the recovery of the analyte must be in control for the LCS. If the native analyte concentration in the MS/MSD exceeds 4x the spike level for that analyte, the recovery data are reported with qualifier and the failure explained in the case narrative.
    - If a MS/MSD is not possible due to limited sample volume then a LCS duplicate may be analyzed. The RPD of the LCS and LCSD must meet the MD/MSD %RPD limit. If the MS/MSD pair cannot be run, the "MS/MSD/DUP – Insufficient Volume" NCM must be applied to the batch.

9.1.4 **If samples in the batch are filtered prior to analysis, the MB and LCS must also be filtered using the same method. If the parent sample is filtered, the MS and MSD must also be filtered using the same method.**

9.2. Instrument QC

9.2.1. Initial Calibration Verification (ICV): An ICV must be analyzed at the beginning of the sequence each day the instrument is used and immediately following the initial calibration of the instrument. The ICV is used to monitor the initial calibration curve. If the result is outside established control limits, the system is out of control and corrective action must occur. The ICV consists of reagent grade water containing a known amount of target analytes that has been injected into the ion chromatography system. The ICV is prepared from a separate stock standard from a different manufacturer than the stock used to prepare the calibration standards. ICV recovery must be within 90-110% of the true value.

9.2.2. Continuing Calibration Verification (CCV): Continuing calibration stability is verified by analyzing a near mid-range calibration verification standard after every ten (10) samples and at the end of the analytical sequence. CCV recovery must be within 90-110%.
If a CCV falls outside control limits for a target anion to be reported, all samples after the last acceptable CCV must be re-analyzed, unless the recovery is high and the associated sample results are non-detect. If results are associated with a failed CCV, they must be reported with qualifier in all cases.

9.2.3. A Continuing Calibration Blank (CCB) is analyzed immediately following each CCV to monitor low level accuracy and system cleanliness. CCB results must

be < MDL. Corrective actions for CCB failures are the same as for Method Blanks (see section 9.1.1).

9.3. Lower Limit of Quantitation (LLOQ): the lowest concentration level that can be measured within stated accuracy limits, varies for each individual analyte anion and as a function of sample size. The LLOQ standard is analyzed after an initial calibration curve. The LLOQ recoveries must be within ±50% of the true value to verify the reporting limit.

10. PROCEDURE

10.1. Sample Preparation

10.1.1. No sample preparation is required for aqueous samples. Aqueous samples are pre-screened for conductivity to determine if any dilutions are required for sample detections to fall within the calibrated range and to avoid overloading the analytical column (see Table 2).

10.1.2. See SOP PT-WC-033 for solid sample preparation using the 1-Hour DI Leaching procedure. Filter the resulting slurry before injecting using a 0.45 um membrane type filter. A Leach Blank and a solid matrix LCS will also be prepared and analyzed along with solid samples.

10.1.3 All samples and QC (MB, LCS and MS/MSD) are filtered using a 0.45 um filter before loading onto the instrument.

10.2. Calibration and Standardization

10.2.1. Establish ion chromatographic operating parameters equivalent to those indicated in Table 1. When using the fast chromatographic run for chloride, bromide, nitrate and sulfate only the guard column is used. Refer to Table 3 for analyte elution order on each column type.

10.2.2. For each analyte of interest, prepare a calibration blank and 6 calibration standards (IC2000) or 8 calibration standards (INTEGRION, IC2100A and IC2100B) by adding accurately measured volumes of one or more stock standards to a volumetric flask and dilution to volume with reagent water. If a sample analyte concentration exceeds the calibration range the sample may be diluted to fall within the range. If this is not possible then three new calibration concentrations must be chosen, two of which must bracket the concentration of the sample analyte of interest. Each attenuation range of the instrument used to analyze a sample must be calibrated individually.

10.2.3. Using an injection volume of 50 uL (IC2000) or 10 uL (INTEGRION, IC2100A and IC2100B) of each calibration standard, tabulate peak height or area responses against the concentration and prepare a calibration curve for each analyte. During this procedure, retention times must be recorded.

10.2.4. Calibration curves are plotted by the instrument software as either peak height or peak area vs concentration. Peak height is preferred for anions that produce sharp, symmetrical peaks though-out the calibrated range. Otherwise, peak area is used.

10.2.5. Curves plots are calculated using either weighted or un-weighted linear regression. The calibration model is chosen based on the best fit to the data to meet the criteria listed below.

- Calculate the %Error for each standard read back to the plotted curve. CHROM software will perform this calculation. The %E for each point above the lowest must be $\leq$ 20%, for the lowest calibration standard the %E must be $\leq$50%.
- The linear correlation coefficient (r^2), must be $\geq$0.995. The absolute value of the intercept must not be above the reporting limit and should be < ½ RL.
- The progression of curve models by preference is:
  Weighted Linear ($1/x^2$)
  Un-weighted Linear
  Linear Forced through Zero

  NOTE: Curves associated with the analysis of any samples from Wisconsin may not be forced through zero. It may be necessary to shorten the calibrated range to achieve linearity with good precision at lower concentrations without forcing the curve plot through the origin.

10.2.6 It is expected that the same curve model should be used for an anion/column combination for each calibration. A need to change the calibration model may indicate that instrument or column maintenance is required.

10.2.7 Retention Time Monitoring

10.2.7.1 The mean retention times for the analytes in the calibration standards will be determined and the retention times of the ICV and CCV will be compared to them.

10.2.7.2 If the retention times of any analyte(s) in the ICV or CCV vary by more than ± 10% from the mean retention time determined from the initial calibration, a new calibration curve will need to be analyzed and all samples not bracketed by a compliant ICV/CCV or CCV/CCV pair will need to be reanalyzed.

10.2.7.3 Daily Retention Time Windows

Establish the center of the retention time windows from the calibration verification at the beginning of the analytical shift. For samples run during the same shift as an initial calibration, use the retention time of the mid-point standard of the initial calibration. Retention time windows can be updated every 12 hours. However, they are usually only updated at the onset of a continuing calibration sequence or after maintenance has been performed.

10.3. Sample Analysis

10.3.1. Any unauthorized deviations from this procedure must also be documented as a nonconformance, with a cause and corrective action described.

10.3.2. Table 1 summarizes the recommended operating conditions for the ion chromatograph. Included in this table are estimated retention times that can be achieved by this method. Other columns, chromatographic conditions, or detectors may be used if the requirements of the QC Table under section 9 are met.

10.3.3. Check system calibration daily and, if required, recalibrate as described in Section 10.2.

10.3.4. Load and inject a fixed amount (10 uL or 50 uL) of settled & filtered sample. Refer to PT-QA-024 for subsampling procedures. If the sample is cloudy then it should be filtered prior to loading into the autosampler polyvial. Filtration will be performed using a 0.45 um filter. If samples are filtered, the method blank and LCS are also filtered. Use the same size loop for standards and samples. Record the resulting peak size in area or peak height units. An automated constant volume injection system may also be used.

10.3.5. The width of the retention time window used to make identifications should be based upon measurements of actual retention time variations of various concentrations. Three times the standard deviation of a retention time can be

used to calculate a suggested window size for each analyte. However, the experience of the analyst should weigh heavily in the interpretation of chromatograms since retention time is concentration dependent for most analytes.

10.3.6. If the response for the peak exceeds the working range of the system, dilute the sample with an appropriate amount of reagent water and reanalyze.

10.3.7. If the resulting chromatogram fails to produce adequate resolution, or if identification of specific anions is questionable, fortify the sample with an appropriate amount of standard and reanalyze.

NOTE: Retention time is affected by concentration. Nitrate and sulfate exhibit the greatest amount of change, although all anions are affected to some degree. In some cases this peak migration may produce poor resolution or identification.

10.3.8. Should more complete resolution be needed between peaks, the first step would be diluted analysis of the sample. In extreme cases, the eluent (7.3 or 7.4) can be diluted. This will spread out the run but will also cause the later eluting anions to be retained longer. The analyst must determine to what extent the eluent is diluted. A calibration curve must be run with the diluted eluent prior to sample analysis. This dilution should not be considered a deviation from the method.

11. CALCULATIONS / DATA REDUCTION

11.1. Prepare a calibration curve for each analyte by plotting instrument response against standard concentration. Compute sample concentration by comparing sample response with the standard curve. Multiply answer by appropriate dilution factor.

11.2. Report only those values that fall between the lowest and the highest calibration standards. Samples exceeding the highest standard should be diluted and reanalyzed.

11.3. Report results in mg/L for aqueous samples and mg/kg for 1-hour leachates and mg/L for 18-hour leachates of solid samples.

11.4. Report

NO2- as N
NO_3^- as N
PO_4^{-3} as P

11.5. When performing manual integration, the reason for it must be clearly documented. For manual integration requirements and documentation refer to SOP CA-Q-S-002.

11.6. If samples for ortho-phosphate analysis have not been filtered in the field within 15 minutes of sampling, results must be qualified as not meeting preservation/holding time requirments.

12. METHOD PERFORMANCE

12.1. The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance

is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2. Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3. A Method Detection Limit (MDL) study, as described in the Detection Limit SOP, PT-QA-007, must be performed initially and whenever a significant change is made to the analytical system. The MDL must be re-evaluated from quarterly MDL points at least every 12 months.

12.4. For Method 300.0, the Linear Calibration Range must be verified every 6 months to ensure that the instrument response is linear beyond the regular calibration range. The criteria used to evaluate the Linear Calibration Range standard is ± 10% of the true value of the standard.

13. POLLUTION CONTROL

13.1. It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention." and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2. This method does not contain any specific modifications that serve to minimize or prevent pollution.

14. WASTE MANAGEMENT

14.1. Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to SOP PT-HS-001. The following waste streams are produced when this method is carried out. The following waste streams are produced when this method is carried out.

14.1.1. Alkaline and/or acidic waste generated by the analysis. This waste is collected in a waste container identified as "Waste Water". This waste is checked with pH paper and neutralized to a final pH between 6 and 9, if needed, and discharged down into a lab sink.

14.2. Contaminated plastic materials such as IC syringes, filters, caps and vials utilized for sample preparation. This waste is placed in trash containers and disposed as regular trash.

TABLE 1

Standard Instrument Operating Parameters

Standard Conditions for IC2000:

Eluent Pump Rate:	1.20 - 1.50 mL/min
Sample Loop:	50 uL (partial loop injection)
Eluent:	1.0mM sodium bicarbonate, 3.5mM sodium carbonate
Detector Output:	Baseline conductivity 15 - 30 uS prior to sample analysis.
Columns:	AS22 (4 x 250mm)

Standard Conditions for INTEGRION, IC2100A and IC2100B:

Eluent Pump Rate:	0.30 mL/min
Sample Loop:	10 uL (partial loop injection)
Eluent:	range of 28 to 36 mM KOH using the Eluent Generator Cartridge
Detector Output:	Total conductivity < 1.0 uS prior to sample analysis.
Columns:	AS18 (2 x 250mm)

Table 2

IC Dilution Table Based on Conductivity

Conductivity(µS)	Dilution Required	Dilution Formula[1]
IC2000		**AS22 Column (4 x 250 mm)**
1 - 300	Undiluted	1 mL of undiluted sample
--	2.5	400 uL sample : 600 uL DI water
300 - 750	5	200 uL sample : 800 uL DI water
750 - 1250	10	100 uL sample : 900 uL DI water
1250 - 2500	25	40 uL sample : 960 uL DI water
2500 - 5000	50	20 uL sample : 980 uL DI water
5000 - 10000	100	10 uL sample : 990 uL DI water
10000 - 20000	250	100 uL(40 uL sample : 960 uL DI water) : 900 uL DI Water
20000 - 40000	500	100 uL(20 uL sample : 980 uL DI water) : 900 uL DI water
IC2100A/IC2100B		**AS18 Column (2 x 250 mm)**
1 - 600	Undiluted	1 mL of undiluted sample
--	2.5	400 uL sample : 600 uL DI water
600 - 1500	5	200 uL sample : 800 uL DI water
1500 - 2500	10	100 uL sample : 900 uL DI water

SOP # with Revision: PT-MT-005 Revision 20
SOP Title: Preparation and Analysis of Mercury by CVAA
Amendment Number: 1

Effective Date of Amendment: 10/13/2020
Append this form to the front of the SOP copy.

CONTROLLED DISTRIBUTION	
COPY # :	**001**
ISSUED TO :	**Pittsburgh SOP Directory**

The following SOP change is in effect as of the stated date. *This form will remain attached to the referenced SOP until such a time that the SOP is updated, approved, and redistributed, at which time it will become part of the historical SOP record.*

1. Briefly explain the reason for the update: The autodigestor was moved and the change of location affected the temperature of the enclosure and block.

2. Category for SOP Change:

☐ Typographical Corrections (Non-Technical) – Retraining Not Required.

☐ Typographical Corrections (Technical- define below) – Retraining is required.

X Procedural Changes (Define Below) – Retraining Required.

3. Summary of Procedure Change (circle to indicate if there are attachments to this form: (No) Yes: # pages attached = ___)

Section 10.3.9 bullet 5 and NOTE under bullet 6 – change temperature setting from 108°C to 96°C.

Does this change result in a Method Modification? Yes (No)
If yes, please explain below.

Any method modification will be incorporated into section 16 of the SOP at the next revision.

THIS UNPUBLISHED WORK BY EUROFINS TESTAMERICA IS PROTECTED BY STATE AND FEDERAL LAW OF THE UNITED STATES. IF PUBLICATION OF THIS WORK SHOULD OCCUR THE FOLLOWING NOTICE SHALL APPLY:

©COPYRIGHT 2020 TESTAMERICA LABORATORIES, INC. D/B/A EUROFINS TESTAMERICA ALL RIGHTS RESERVED.

1. SCOPE AND APPLICATION

1.1. This procedure describes the preparation and analysis of mercury (Hg, CAS # 7439-97-6) by Cold Vapor Atomic Absorption Spectroscopy (CVAA) using SW-846 Methods 7470A 7471A and 7471B and MCAWW Method 245.1. The TestAmerica Pittsburgh facility utilizes hot block digestion for all preparations.

1.2. CVAA analysis provides for the determination of total mercury (organic and inorganic). The combination of the oxidants, potassium permanganate and potassium persulfate, has been found to give 100% recovery with both types of compounds. Detection limits, sensitivity and optimum concentration ranges for mercury analysis will vary with the matrices, instrumentation and volume of sample used.

1.3. Method 7470A is applicable to the preparation and analysis of mercury in ground water, aqueous samples, wastes, wipes, TCLP, SPLP and other leachates/extracts. Certain solid and sludge type wastes may also be analyzed using this method. Methods 7471A and 7471B are applicable to the preparation and analysis of mercury in soils, sediments, bottom deposits, sludge-type materials wipes, and tissue matrices. All matrices require sample preparation prior to analysis.

1.4. Method 245.1 is applicable to the determination of mercury in drinking, surface and saline waters, domestic and industrial wastes. All matrices require sample preparation prior to analysis.

1.5. The TestAmerica reporting limit for mercury in aqueous matrices is 0.0002 mg/L. The reporting limit in solid matrices is 0.033mg/kg based on a 0.6g sample aliquot (wet weight). The reporting limit for wipes is 0.02 ug/wipe.

1.6. On occasion clients may request modifications to this SOP. Any modification to this procedure must be approved by the QA department of the Laboratory or Technical Director, and documented fully in an NCM.

2. SUMMARY OF METHOD

2.1. This SOP describes a technique for the determination of mercury in solution. The procedure is a physical method based on the absorption of radiation at 253.7 nm by mercury vapor. A representative portion of the sample is digested in acid. Organic mercury compounds are oxidized with potassium permanganate and potassium persulfate and the mercury reduced to its elemental state with stannous chloride and aerated from solution in a closed system. The mercury vapor passes through a cell positioned in the light path of an atomic absorption spectrophotometer. Absorbance is measured as a function of mercury concentration. Concentration of the analyte in the sample is determined by comparison of the sample absorbance to the calibration curve (absorbance vs. concentration).

3. DEFINITIONS

3.1. Dissolved Metals - Those elements which pass through a 0.45 um membrane. (Sample is acidified after filtration).

3.2. Suspended Metals - Those elements which are retained by a 0.45 um membrane.

3.3. Total Metals - The concentration determined on an unfiltered sample following digestion.

3.4. TALS – TestAmerica Laboratory Information Management System

3.5. NCM – Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.6. Refer to the glossary in the Laboratory Quality Manual (PT-QA-M-001) for additional definitions.

4. INTERFERENCES

4.1. Sulfide may pose an interference with this analysis. Potassium permanganate, which is used to breakdown organic mercury compounds, also eliminates possible interferences from sulfide. Concentrations as high as 20 mg/L of sulfide, as sodium sulfide, do not interfere with the recovery of inorganic mercury from reagent water.

4.2. Copper has also been reported to interfere; however, copper concentrations as high as 10 mg/L had no effect on the recovery of mercury from spiked samples.

4.3. Chlorides can cause a positive interference. Seawaters, brines and industrial effluents high in chlorides require additional permanganate (as much as 25 mL) because, during the oxidation step, chlorides are converted to free chlorine, which also absorbs radiation at 253.7 nm. Care must be taken to ensure that free chlorine is absent before the mercury is reduced and swept into the cell. This is accomplished by adding excess hydroxylamine reagent (25 mL) and purging the sample head space before stannous chloride is added. Both inorganic and organic mercury spikes have been quantitatively recovered from seawater using this technique. Alternatively, samples may be allowed to stand for at least one hour under a hood (without active purging) to remove the chlorine.

Note: Sufficient addition of permanganate is apparent when the purple color persists at least 15 minutes. Some samples may require dilution prior to digestion due to extremely high concentrations of chloride.

4.4. Interference from certain volatile organic materials that absorb at this wavelength may also occur. If suspected, a preliminary run without stannous chloride can determine if this type of

interference is present. While the possibility of absorption from certain organic substances present in the sample does exist, this problem is not routinely encountered. This is mentioned only to caution the analyst of the possibility. If this condition is found to exist, the mercury concentration in the sample can be determined by subtracting the result of the sample run without the reducing reagent (stannous chloride) from that obtained with the reducing reagent.

4.5. Samples containing high concentrations of oxidizable organic materials, as evidenced by high COD levels, may not be completely oxidized by this procedure. When this occurs the recovery of mercury will be low. The problem can be eliminated by reducing the volume of original sample used.

4.6. The most common interference is laboratory contamination, which may arise from impure reagents, dirty glassware, improper sample transfers, dirty work areas, etc. Be aware of potential sources of contamination and take appropriate measures to minimize or avoid them.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2. Samples that contain high concentrations of carbonates or organic material, or samples that are at elevated pH, can react violently when acids are added.

5.3. Do not look directly into the beam of the Hg lamp. The UV light that these lamps radiate is harmful to the eyes.

5.4. The following is a list of the materials used in this method, which have a serious or significant hazard rating. This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material (1)	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Mercury (1,000 PPM in Reagent)	Oxidizer Corrosive Poison	0.1 mg/m^3 Ceiling (Mercury Compounds)	Extremely toxic. Causes irritation to the respiratory tract. Causes irritation. Symptoms include redness and pain. May cause burns. May cause sensitization. Can be absorbed through the skin with symptoms to parallel ingestion. May affect the central nervous system. Causes irritation and burns to eyes. Symptoms include redness, pain, and blurred vision; may cause serious and permanent eye damage.
Sulfuric Acid	Corrosive Oxidizer Dehydrator Poison	1 mg/m^3-TWA	Inhalation produces damaging effects on the mucous membranes and upper respiratory tract. Symptoms may include irritation of the nose and throat, and labored breathing. Symptoms of redness, pain, and severe burn can occur. Contact can cause blurred vision, redness, pain and severe tissue burns. Can cause blindness.
Nitric Acid	Corrosive Oxidizer Poison	2 ppm-TWA 4 ppm-STEL	Nitric acid is extremely hazardous; it is corrosive, reactive, an oxidizer, and a poison. Inhalation of vapors can cause breathing difficulties and lead to pneumonia and pulmonary edema, which may be fatal. Other symptoms may include coughing, choking, and irritation of the nose, throat, and respiratory tract. Can cause redness, pain, and severe skin burns. Concentrated solutions cause deep ulcers and stain skin a yellow or yellow-brown color. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.

Hydrochloric Acid	Corrosive Poison	5 PPM-Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failure, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Potassium Permanganate	Oxidizer	5 mg/m^3 for Mn Compounds	Causes irritation to the respiratory tract. Symptoms may include coughing, shortness of breath. Dry crystals and concentrated solutions are caustic causing redness, pain, severe burns, brown stains in the contact area and possible hardening of outer skin layer. Diluted solutions are only mildly irritating to the skin. Eye contact with crystals (dusts) and concentrated solutions causes severe irritation, redness, and blurred vision and can cause severe damage, possibly permanent.
Stannous Chloride	Irritant	2 mg/m^3 TWA as Tin	Causes irritation to the respiratory tract. Can irritate skin and eyes. Symptoms include coughing and shortness of breath. Contact with skin and/or eyes may cause redness, itching and pain.
Potassium Persulfate	Oxidizer	None	Causes irritation to the respiratory tract. Symptoms may include coughing, shortness of breath. Causes irritation to skin and eyes. Symptoms include redness, itching, and pain. May cause dermatitis, burns, and moderate skin necrosis.
1 – Always add acid to water to prevent violent reactions.			
2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.5. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.6. Mercury is a highly toxic element that must be handled with care. The analyst must be aware of the handling and clean-up techniques before working with mercury. Since

mercury vapor is toxic, precaution must be taken to avoid its inhalation, ingestion or absorption through skin. All lines should be checked for leakage and the mercury vapor must be vented into a hood or passed through a mercury absorbing media.

5.6.1. Instrument carrier gas passes through a solid potassium permanganate trap before being released into the lab atmosphere.

5.7. Exposure to chemicals must be maintained as low as reasonably achievable. Therefore, unless they are known to be non-hazardous, all samples should be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.8. The preparation of standards and reagents will be conducted in a fume hood with the sash closed as far as the operation will permit.

5.9. All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

5.10. Cylinders of compressed gas must be handled with caution, in accordance with local regulations. It is recommended that, wherever possible, cylinders be located outside the laboratory and the gas led to the instrument through approved lines.

5.11. The CVAA apparatus must be properly vented to remove potentially harmful fumes generated during sample analysis. See 5.6.1 above.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should be used only when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if, with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1. Temperature controlled hot blocks, capable of maintaining a temperature of 95 ± 3℃ for 2 hours

6.2. Environmental Express Autoblock automated sample digestion system with Autoblock Plus software

6.3. Automated Mercury Analysis System, Leeman Quick Trace M-7600 or equivalent

6.4. Disposable, sealable sample containers (Environmental Express)

6.5. Argon gas supply (ultrahigh purity-grade)

6.6. Calibrated automatic pipettes or Class A glass volumetric pipettes

6.7. Class A volumetric flasks

6.8. Thermometer (capable of accurate readings at 95°C)

6.9. Disposable cups or tubes, and disposable watch glasses

6.10. Filter paper, Whatman grade 41 or Fisher Scientific grade Q8

6.11. Class A graduated cylinders

6.12. Balance capable of weighing to the nearest 0.01 g.

7. REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should be used only when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard.

Reagent grade, or higher, chemicals must be used unless otherwise indicated.

7.1. Reagent water must be produced by a Millipore DI system or equivalent. Reagent water must be free of the analytes of interest as demonstrated through the analysis of method blanks.

7.2. Stock (1000 ppm) mercury standards (in 2% HNO_3) are purchased as custom TestAmerica solutions. A standard must be purchased from two separate sources, one for calibration and spiking and another for calibration verification. All standards must be stored in FEP fluorocarbon or previously unused polyethylene or polypropylene bottles. Stock standard solutions must be replaced prior to the expiration date provided by the manufacturer. If no expiration date is provided, the stock solutions may be used for up to one year and must be replaced sooner if verification from an independent source indicates a problem.

7.3. Intermediate mercury standard (10 ppm): Take 1 mL of the stock mercury standard (7.2) and dilute to 100 mL with reagent water. The intermediate standard must be prepared daily and must be prepared in a matrix of 2% HNO_3. This acid (2 mL of concentrated HNO_3) must be added to the flask/bottle before the addition of the stock standard aliquot.

7.3.1. A Second Source Intermediate standard at 10 ppm is prepared in the same way, using the second source stock standard, for use in preparing the Initial Calibration Verification (ICV) standard.

7.4. Working mercury standard (0.1 ppm): Take 1 mL of the intermediate mercury standard (7.3) and dilute to 100 mL with reagent water. The working mercury standard must be made daily and must be prepared in a matrix of 0.15% HNO_3. This acid (150 uL of concentrated HNO_3) must be added to the flask/bottle before the addition of the stock standard aliquot. A second source working standard is prepared at 0.1 ppm for preparation of the ICV. Working standard must be prepared fresh daily.

7.5. The calibration standards listed in Table I must be prepared fresh daily from the working standard (7.4) by transferring 0, 0.2, 0.5, 1.0, 5.0 and 10.0 mL aliquots of the working mercury standard into 100 mL flasks and diluting to volume with reagent water. See Table 1 for the preparation of the ICV, CCV and RLV/CRA standards. Calibration and QC standards must be prepared fresh daily.

Note: Alternate approaches to standard preparation may be taken and alternate volumes of standard may be prepared as long as the accuracy and final standard concentrations as detailed in Table I are maintained. For example, automated mercury systems do not require 100 mL of standard and therefore smaller volumes may be generated to reduce waste generation.

7.6. The initial calibration verification standard (ICV) must be made from a different stock solution than that of the calibration standards and prepared daily.

7.7. Nitric acid (HNO_3), concentrated, trace metal grade or better.

Note: If a high reagent blank is obtained, it may be necessary to distill the nitric acid.

7.8. Sulfuric acid (H_2SO_4), concentrated, trace metal grade or better.

7.8.1. Sulfuric acid, 0.5 N: Dilute 14.0 mL of concentrated H_2SO_4 to 1 liter with reagent water.

7.9. Hydrochloric acid (HCl), concentrated, trace metal grade or better.

7.10. Aqua regia: Prepare by carefully adding three parts concentrated HCl to one part concentrated HNO_3. Must be prepared fresh every 48 hours or sooner in aliquots of 500 to 1000 mls.

7.11. Stannous chloride solution: Add 200 g of stannous chloride to 2 L of 10% hydrochloric acid. Expiration date for the stannous chloride solution is 3 months from the date of preparation.

7.12. Sodium chloride, NaCl

7.13. Hydroxylamine hydrochloride, $HONH_2 \bullet HCl$,

7.13.1. Sodium chloride-hydroxylamine hydrochloride - Clearing Solution: Add 12 g of sodium chloride and 12 g of hydroxylamine hydrochloride to every 100 mL of reagent water. Expiration date for the sodium chloride-hydroxylamine solution is 3 months from the date of preparation.

7.14. Potassium permanganate, $KMnO_4$

7.14.1. Potassium permanganate, 5% solution (w/v): Dissolve 5 g of potassium permanganate for every 100 mL of reagent water. Expiration date for the potassium permanganate 5% solution is 3 months from the date of preparation.

7.15. Potassium persulfate, $K_2S_2O_8$

7.15.1. Potassium persulfate, 5% solution (w/v): Dissolve 5 g of potassium persulfate for every 100 mL of reagent water. Solution should be gently heated to dissolve crystals. Expiration date for the potassium persulfate 5% solution is 3 months from the date of preparation.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1. Listed below are the holding times and preservation requirements:

Matrix	Sample Container	Min. Sample Size	Preservation	Holding Time
Water	Plastic or glass	250 mL	pH <2 with HNO3	28 days from sampling to analysis
TCLP Leachates	Plastic	250 mL	pH <2 with HNO3	28 days from start of TCLP Leach
Soils/ Sediments	4oz Jar	5 grams	Cool to >0 but ≤ 6.0ºC	28 Days from collection to analysis
Wipes	2oz Jar	1 wipe	Cool to >0 but ≤ 6.0ºC	28 Days from collection to analysis
Tissues	4oz Jar	5 grams	Frozen	Freeze up to 1 year, then 28 Days from thaw date to analysis

8.2. For dissolved mercury analysis, the samples should be filtered through a 0.45 µm filter prior to preservation. Filtration should be done in the field within 15 minutes of collection. If the laboratory filters the samples, this process will occur as soon as possible after receipt. A filtered blank must be processed with laboratory filtered samples. The "Filtration – Field Filtered" NCM shall be completed if the laboratory filters the samples.

NOTE: If a sample being analyzed for dissolved mercury is found to contain sediment the analyst should contact their supervisor or group leader. The client should be notified of the problem to decide how to treat the sample.

8.3. Dissolved mercury samples that are filtered directly into a nitric acid preserved bottle may be digested immediately.

9. QUALITY CONTROL

9.1. The following quality control samples are prepared with each batch of samples.

QC PARAMETER	FREQUENCY	ACCEPTANCE CRITERIA	CORRECTIVE ACTION
ICV	Beginning of every analytical run	%Recovery: 7470A/7471A/B: 90 - 110% 245.1: 95 - 105%	Re-inject once, if failure repeats, terminate analysis; correct the problem; recalibrate, re-prepare batch
ICB	Beginning of every analytical run, immediately following the ICV	The result must be within +/- RL from zero	Re-inject once, if failure repeats, terminate analysis; correct the problem; recalibrate, re-prepare batch
RLV/CRA	Beginning of every analytical run, immediately following the ICB	70 – 130% recovery for 7470A 50-150% for 245.1 & 7471A/B	Re-inject once, if failure repeats, terminate analysis; correct the problem; recalibrate, re-prepare batch Note exception under section 9.7

QC PARAMETER	FREQUENCY	ACCEPTANCE CRITERIA	CORRECTIVE ACTION
CCV	Every 10 samples and at the end of the run	90 - 110 % recovery	Re-inject once, if failure repeats, terminate analysis; Correct the problem; Recalibrate or rerun all samples not bracketed by acceptable CCV or re-prepare batch Note exceptions under section 9.6.
CCB	Immediately following each CCV	The result must be within +/- RL from zero	Re-inject once, if failure repeats, terminate analysis; Correct the problem; Recalibrate or rerun all samples not bracketed by acceptable CCB or re-prepare batch Note exceptions under section 9.6.
Method Blank	One per sample preparation batch of up to 20 samples	The result must be $\leq$ the RL for method 7470A & 7471A/B or $\leq$ 2.2 x MDL for 245.1. Sample results greater than 10x the blank concentration are acceptable.	Re-inject once, if failure repeats, re-prepare and reanalyze affected samples. Note exceptions under section 9.2.
Laboratory Control Sample (LCS)	One per sample preparation batch of up to 20 samples.	%Recovery Limits: 7470A/7471A/B: 80 - 120 % 245.1: 85 – 115%	Re-inject once, if failure repeats, re-prepare and reanalyze all samples associated with the LCS. Note exceptions under section 9.3.

QC PARAMETER	FREQUENCY	ACCEPTANCE CRITERIA	CORRECTIVE ACTION
Matrix Spike	One per sample preparation batch of up to 20 samples for 7470A and 7471A/B and one per 10 samples for 245.1	%Recovery Limits: 7470A 75 – 125% 7471A/B 80 – 120% 245.1 70 – 130%	In the absence of client specific requirements, flag the data. Note exceptions under section 9.4.
Matrix Spike Duplicate	See Matrix Spike	% Recovery as for MS above; RPD ≤ 20%.	See Corrective Action for Matrix Spike.

9.2. Method Blank (MB) - The method blank is carried through the entire analytical procedure, including preparation and analysis. The method blank is used to identify any system and process interferences or contamination of the analytical system that may lead to the reporting of elevated analyte concentrations or false positive data. The method blank is prepared using a known clean matrix, laboratory reagent water along with aqueous samples or Teflon boiling chips along with solid samples. The method blank should not contain any mercury at or above the reporting limit for methods 7470A and 7471A/B, or above 2.2 x the MDL for method 245.1. If the MB result is above the required method limit, re-inject it once. If failure repeats, follow corrective actions below.

- If the method blank is contaminated and associated sample concentrations are > 10x the MB concentration, results may be reported and using the “Method Blank – Report, 10X” NCM.
- If mercury is not detected above the RL in the samples associated with an unacceptable method blank, the data may be reported with qualifiers and using the “Method Blank – Report, ND” NCM.
- If neither of the above situations applies, and reanalysis is not possible due to sample volume or holding time, the client must be notified. Results must be properly qualified in the report and the nonconformance described in the case narrative.

NOTE: See Appendix C for information on contamination control.

9.3. Laboratory Control Sample (LCS) - The LCS (referred to as a Laboratory Fortified Blank in 245.1) is a blank that is spiked with a known concentration of mercury and carried through the same preparation and analysis procedures as the samples. The LCS is used to monitor the accuracy of the analytical process and is prepared in the same clean matrix as the Method Blank. On-going monitoring of the LCS results provides evidence that the laboratory is performing the method within acceptable accuracy and precision guidelines. CCV results can be reported as LCS results since all CCVs (as well as all other standards) are processed through the sample preparation step with the field samples. No more than 20 samples can be associated with one CCV used for the purpose of reporting LCS data.

- If the LCS is outside established control limits given in the table above, re-inject the LCS once. If failure repeats, follow corrective actions below.
- In the instance where the LCS recovery is > 120% (7470A/7471A/B) or > 115% (245.1), but below 140%, and sample results are < RL, reanalysis is not required and the data may be reported with qualifiers and using the “LCS/CLSD - %R High” NCM.
- Corrective action will be re-preparation and reanalysis of the batch unless the client agrees that other corrective action is acceptable. If reanalysis is not possible due to sample volume or holding time, the client must be notified. Results must be properly qualified in the report and the nonconformance described in the case narrative.

9.4. Matrix Spike/Matrix Spike Duplicate (MS/MSD) - A matrix spike (MS) is a field sample to which known concentrations of target analytes have been added (referred to as a Laboratory Fortified Matrix in 245.1). A matrix spike duplicate (MSD) is a second aliquot of the same sample (spiked identically as the MS) prepared and analyzed along with the sample and matrix spike. Some client specific data quality objectives (DQO’s) may require the use of sample duplicates in place of or in addition to MS/MSD’s. The MS/MSD results are used to determine the effect of a matrix on the precision and accuracy of the analytical process. Due to the potential variability of the matrix of each sample, these results may have immediate bearing only on the specific sample spiked. Samples identified as field blanks cannot be used for MS/MSD analysis. Spiking levels are provided in Table I.

- If analyte recovery or RPD falls outside the acceptance ranges given in the table above, the recovery of that analyte must be in control for the LCS. If the LCS recovery is within limits, then the laboratory operation is in control and the results may be accepted. If the recovery of the LCS is outside limits, corrective action must be taken. Corrective action will include re-preparation and reanalysis of the batch. MS/MSD results which fall outside the control limits must be addressed in the narrative and qualified.

- If the parent sample concentration is >4x the spiked concentration, the spike cannot be accurately recovered. The results may be reported using the "MS/MSD – High Targets" NCM.

- If there is insufficient sample volume to perform and MS and MSD with the batch, an LCSD should be performed and the situation documented with the "MS/MSD/DUP – Insufficient Volume" NCM.

9.5. Initial Calibration Verification (ICV/ICB) - Calibration accuracy is verified by analyzing a second source standard (ICV). An ICB is analyzed immediately following the ICV to monitor low level accuracy and system cleanliness. (The ICV is equivalent to the Quality Control Sample (QCS) and the first Initial Performance Check (IPC) specified in method 245.1.) See the Table above for control limits.

- If either the ICV or ICB fail to meet criteria, it should be re-injected once. If failure repeats, the analysis should be terminated, the problem corrected and the instrument recalibrated. If the cause of the ICV or ICB failure was not directly instrument related the corrective action will include re-preparation of the associated samples.

9.6. Continuing Calibration Verification (CCV/CCB) - Calibration accuracy is monitored throughout the analytical run through the analysis of a known standard and blank after every 10 samples and at the end of the analytical sequence. The CCV must be a mid-range standard at a concentration different than that of the ICV. Each CCV and CCB analyzed must reflect the conditions of analysis of all associated samples. Sample results may only be reported when bracketed by valid ICV/CCV and ICB/CCB pairs. If a mid-run CCV or CCB fails, it should be re-injected once. If failure repeats, the analysis must be terminated, the problem corrected, the instrument recalibrated, the calibration verified and the affected samples reanalyzed. If the cause of the CCV or CCB failure was not directly instrument related the corrective action will include re-preparation of the associated samples.

- If a bracketing CCB is contaminated, but the associated samples are non-detect, results may be reported with qualification and NCM similar to section 9.2 for MB.

- If a bracketing CCV has recovery above 110%, but the associated samples are non-detect, results may be reported with qualification and NCM similar to section 9.3 for LCS.

9.7. A Reporting Limit Verification Standard (RLV) or Contract Required Quantitation Standard (CRA) is used to evaluate the calibration accuracy at the laboratory reporting limit. A standard at the reporting limit concentration is injected immediately after the analysis of the ICB. This standard may also be analyzed at the end of the analytical sequence. Recovery must be within 70-130% for method 7470A, or 50-150% for methods 245.1 and 7471A/B. If the RLV/CRA recovery is outside control limits, re-inject the standard once. If failure

repeats, follow corrective actions below. Recalibrate the instrument, and re-digest the batch if recalibration does not correct the failure.

- If recovery is low, all samples must be reanalyzed.
- If recovery is high, samples with non-detect results may be reported with the "Low-Level Std – Outside Criteria" NCM. All samples that have results above the RL must be re-analyzed.

9.8. Method of Standard Addition (MSA) -This technique involves adding known amounts of standard to one or more aliquots of the sample prior to preparation. This technique compensates for a sample interferent that may enhance or depress the analyte signal, thus producing a different slope from that of the calibration standards. It will not correct for additive interferences which cause a baseline shift. Refer to Section 10.5.10 for additional information on when full 4 point MSA is required as well as Appendix A for specific MSA requirements.

10. PROCEDURE

10.1. Calibration and Standardization

10.1.1. Calibration standards must be processed through the preparation procedure as described in Section 10.2, 10.3, or 10.4 along with the samples.

10.1.2. Due to the differences in preparation protocols separate calibration and calibration verification standards must be prepared for aqueous and solid matrices.

10.1.3. Calibration must be performed daily (every 24 hours). The instrument calibration date and time must be included in the raw data.

10.1.4. Set up the instrument with the operating parameters recommended by the manufacturer. Allow the instrument to become thermally stable before beginning calibration (approximately 30 minutes of warm-up is required). Refer to CVAA instrument manual for detailed setup and operation protocols.

10.1.5. Calibrate the instrument according to instrument manufacturer's instructions, using a minimum of five standards and a blank. One standard must be at or below the reporting limit. Analyze standards in ascending order beginning with the blank. Refer to Section 7.5 and Table I for additional information on preparing calibration standards and calibration levels.

10.1.6. The calibration curve is plotted by the instrument software as absorbance vs. concentration using linear regression.

- The curve must have a correlation coefficient of ≥0.995 or the instrument shall be stopped and recalibrated prior to running samples. Sample results cannot be reported from a curve with an unacceptable correlation coefficient.

- Calculate the concentration of each calibration standard from the final calibration curve. Calculate the %Error for each point. All points except the lowest must have a %Error of ≤20%. The lowest standard (RL level) must have a %Error ≤ 50%.

  - %Error is the absolute value of the difference between the calculated concentration and the true concentration divided by the true concentration x100%.

    For example, if the 0.20mg/L standard reads back as 0.17mg/L:

    [(0.20 – 0.17)/0.20] x 100% = 15%

10.1.7 Refer to Section 9.5 and 9.6 for calibration verification procedures, acceptance criteria and corrective actions. The NELAC requirement for verification of the initial calibration at varied concentrations is met daily since the ICVs, CCVs, and RLV/CRA are all at different concentrations.

10.2. Aqueous Sample Preparation - Manual

10.2.1. All calibration and calibration verification standards (ICV, ICB, CCV, CCB, RLV/CRA) are processed through the digestion procedure as well as the field samples.

10.2.2. Prepare calibration standards as in section 7.5 above and Table 1, and transfer into a series of sample digestion containers.

10.2.3. Transfer 50 mL of well-mixed sample or standard to a clean sample digestion bottle. Refer to PT-QA-024 for subsampling procedures.

Note: Reduced sample volumes can be used as long as a representative sample can be obtained and the reagent levels are adjusted to maintain the same sample to reagent ratio. All samples and standards must be processed in the same manner.

10.2.4. To the LCS container, add 1.25 mL of the 0.1 ppm working standard (7.4) to 50 mL of reagent water. To the MS and MSD containers, add 0.50 mL of the 0.1 ppm working standard to 50 mL of parent sample.

10.2.5. Add 2.5 mL of concentrated H_2SO_4 and 1.25 mL of concentrated HNO_3 mixing after each addition.

10.2.6. Add 7.5 mL of potassium permanganate solution. For samples high in organic materials or chlorides, this amount of permanganate may not be sufficient. Check samples after 15 minutes. If the purple color has disappeared, dilute the sample and begin the digestion again.

10.2.7. Add 4 mL of potassium persulfate solution for a 50 mL sample.

10.2.8. Confirm that the hot block is within the proper temperature range by checking the liquid-in-glass thermometer in the block. Place the sample rack in the block and heat the samples for two hours in a hot block at 95 ± 3℃. Record both the observed and corrected temperature reading in the batch information in TALS,

10.2.9. Cool samples for approximately 15 minutes.

10.2.10. Add 3 mL of sodium chloride-hydroxylamine hydrochloride “clearing solution” to the samples to reduce the excess permanganate (the permanganate has been reduced when no purple color remains). Add this solution in 3 mL increments until the permanganate is completely reduced (i.e. solution is colorless).

10.2.11. Once the samples are clear, adjust the final digestate volume to 50 ml with reagent water.

10.2.12. **NOTE:** All known difficult water matrices (ie. Safety Kleen Total and TCLP waters) are prepared at a 10 fold dilution, 5 mls of sample diluted to a final volume of 50 mLs with reagent water. A difficult matrix is one that contains a large amount of debris, sediment or has an extremely high pH (caustic in nature).

10.3. Aqueous Sample Preparation - Autoblock

10.3.1. Power on the Autoblock and open Autoblock Plus software. The software will not open unless the instrument is powered on.

- A Warning message about going to home position will appear – click OK

10.3.2. Expired service items list will appear (waste drum) – click OK. After addressing the necessary service items (empty waste drum), Click **Service Interface** → go to **Maintenance Screen** → and click “press” next to the service item(s) to be updated.

- A pop-up will appear asking if you want to update the service date, click OK.

10.3.3. Exit the Maintenance Screen and go to **Manual Interface**.

- A Warning message about going to home position will appear – click OK

10.3.3.1. All reagent tubes need to be primed. Check that all reagents are full enough to complete the batch. Click on the desired reagent, then click "move to drain". Move the rack position to "fill". Change the injection amount to "30.0mL" and press "inject". Repeat for all reagents.

10.3.4. Exit the Manual Interface and go to **Operator Test**. Click on "select method" and choose *245.1 and 7470A PIT.mtd*.

10.3.4.1. Type in the "batch number" and "operator name". (Initials may be used.)

10.3.4.2. Select all cell locations where samples will be placed.

- All samples and QC have an initial volume of 25mL

10.3.5. All calibration and calibration verification standards (ICV, ICB, CCV, CCB, RLV/CRA) are processed through the digestion procedure as well as the field samples. Prepare calibration standards as in section 7.5 above and Table 1.

10.3.6. Transfer 25 mL of well-mixed sample, standard, or QC to a clean sample digestion tube. Refer to PT-QA-024 for subsampling procedures.

Note: Reduced sample volumes can be used as long as a representative sample can be obtained and the reagent levels are adjusted to maintain the same sample to reagent ratio. All samples and standards must be processed similarly.

10.3.7. To the LCS container, add 0.625 mL of the 0.1 ppm working standard (7.4) to 25 mL of reagent water. To the MS and MSD containers, add 0.25 mL of the 0.1 ppm working standard to 25 mL of parent sample.

10.3.8. Make sure that the following have green rectangles next to them:

- Pump area leak
- Drain area leak
- Cabinet pressurized – the compressor should stay on always
- Blower overpressure – the fan will turn on automatically

10.3.9. Hit **Go**. The Autoblock will complete the following steps:

- Inject 0.625 mL of nitric acid in each sample
- Inject 1.25 mL of sulfuric acid in each sample
- Inject 3.75 mL of potassium permanganate in each sample
  NOTE: Check for the persistence of purple color at a practical point in the digestion before the cooling. If the color has disappeared, re-digest the samples at a dilution.
- Inject 2.0 mL of potassium persulfate in each sample
- Sample racks will rise to highest position while autoblock heats up to 108℃
- Once temperature is reached, sample racks will lower into the hotblock and cook for 2 hours.
  NOTE: Block is set at 108℃ to maintain un-capped sample temperatures are 85±3℃.
  NOTE: Temperature is maintained at 85 ±3°C rather than 95±3°C because the digestion vessels cannot be covered on the Autoblock.
- After digestion, sample racks will be brought to highest position to cool for 20 minutes.
- 1.5 mL of clearing solution will be injected after the samples are cooled.
- Analyst is responsible for bringing samples up to a final volume of 25mL.

10.3.10. After sample digestion is complete, clean the reagent tubes with laboratory reagent water using the same procedure as for priming in section 10.3.3.1.

NOTE: Use Clearing Solution first when cleaning the potassium permanganate line, followed by water rinse.

10.3.11. Turn off the Autoblock and “abort” the Autoblock Plus software.

10.4. Solid Sample Preparation

10.4.1. Prepare calibration standards as in section 7.5 above and Table 1, and transfer into a series of sample digestion containers.

10.4.2. Transfer 0.6 g of a well-mixed sample into a clean sample digestion container. Refer to PT-QA-024 for proper subsampling procedures.

10.4.2.1. For wipes, add the entire contents of the sample jar into a clean sample digestion container. For sediment samples, 1.2 g of well-mixed sample is used. TCLP leachates from waste samples are digested by this procedure using 0.6 mL initial volume.

10.4.3. To the LCS container, add 2.5 mL, and to the MS, and MSD containers, add 1.0 mL of 0.1 ppm working standard (7.4).

10.4.4. Add 5 mL of reagent water and 5 mL of Aqua Regia reagent (7.10).

10.4.5. Confirm that the hot block is within the proper temperature range by checking the liquid-in-glass thermometer in the block. Place the sample rack in the block and heat the samples for 2 minutes at 95 ± 3℃.

10.4.6. Remove the rack from the block and allow the samples to cool slightly. Add 50 mL of reagent water and 15 mL of potassium permanganate solution (7.14.1) to each sample. Let stand at least 15 minutes.

10.4.7. Check the samples for the persistence of the purple color. Add additional portions of permanganate solution, if needed, until the purple color persists for at least 15 minutes.

NOTE: If additional permanganate solution is added to samples, an equal amount must also be added to standards and blanks.

10.4.8. Add 8 mL of potassium persulfate solution (7.15.1) and mix thoroughly.

10.4.9. Return racks to the hot blocks and heat for 30 minutes after samples reach 95 ± 3℃.

10.4.10. After 30 minutes, remove the racks and allow samples to cool.

10.4.11. Add 6 mL of hydroxylamine hydrochloride solution (7.13.1) to reduce excess permanganate.

10.4.12. Bring standards, QC and samples up to a volume of 100 mL with reagent water.

10.4.13. Alternate final volumes may be used as long as the standards and samples are treated the same way and reagent volumes are adjusted proportionally.

10.5. Sample Analysis:

Note: The samples must be allowed to cool to room temperature prior to analysis or a decrease in the response signal can occur.

Note: If digestates are not free from particulates after cooling and settling, and require filtration prior to being introduced on the instrument, the associated MB and LCS must also be filtered.

10.5.1. Quick Trace Mercury Analyzer M-7600 Instrument set up:

10.5.1.1. Go to the **Reporting Options** tab and deselect **replicates** (Hit “X” and then “yes” to save.)

10.5.1.2. Go to **Sequence Parameters**, select **smart rinse**, change the µAbs to 75000 and select **abort on over-range**, then save.

10.5.1.3 Go to **Method Editor**, click on the **standards** tab, select **Coeff. of Determination (r^2) limit**, and under **Calibration Parameters**, select **pause analysis after first calibration pending confirmation to continue**. Save.

10.5.1.4 Place the rinse tube in 10% HCl rinse solution and the Stannous Chloride line in DI water.

10.5.1.5 Go to the **Instrument Control/Maintenance Log**

- Click on the **Autosampler** tab and turn on the pump.
- Click on the **Analyzer** tab and turn on the pump.

NOTE: Set speed to 50% to reduce unnecessary wear on peristaltic tubing.

10.5.1.6 Clamp down the Stannous Chloride line on the analyzer’s pump and watch for a steady flow of DI water into the analyzer (no air bubbles).

10.5.1.7 Go to the **Instrument Control/ Maintenance Log**, click the **Autosampler** tab. Under **move sample probe** select **down**.

10.5.1.8 Clamp sample line (probe line) down on the pump and check for a steady flow (no air bubbles).
Note: the post in the gas-liquid separator (GLS) should start to moisten.
10.5.1.9 Select **wet the post** after about a half inch of water accumulates in the GLS.
10.5.1.10 Once the post is lubricated, clamp the two rinse tubes down on the analyzer pump, and release both the stannous line and sample line to drain the water.
10.5.1.11 Re-clamp all four tubes after the water has drained sufficiently.
10.5.1.12 Place the Stannous Chloride line into the Stannous Chloride solution.
10.5.1.13 Attach the gas line to the GLS and let the instrument run for a few minutes.
10.5.1.14 Go to the **Instrument Control/ Maintenance Log**, click the **Analyzer** tab, select **zero instrument**, then click the graph button to observe the graph of the instrument readings.
10.5.1.15 Allow the instrument to warm up for at least 30 minutes.

10.5.2. Creating a Worksheet:
10.5.2.1 Open Leeman QuickTrace Mercury Analysis System on desktop.
10.5.2.2 Create a new file:
- Open a worksheet, select **new form**, click the search button, select **TestAmerica Template**, and name the run.
- If **TestAmerica Template** does not automatically open go to OS (C:) → users → public → public documents → Teledyne CETAC → Quicktrace → templates → TestAmerica.
- Name the run as follows: HGZ81012A.
  HGZ = instrument name
  8 = year
  10 = month
  12 = day
  A = first run that day (B = 2nd, C = 3rd, etc)

10.5.2.3 Scan the ICV, ICB, CRA, CCV, and CCB from the curve batch sheet into the worksheet and use the drop down under **sample type** to select the correlating QC option.
- CRA = CRDL Standard under sample type

NOTE: The six point curve is included in the template, however, the six points will need to be scanned from the curve batch sheet after you upload your analytical run.
10.5.2.4 Scan samples into worksheet
- Sample type is left **unknown** except for MB, LCS, and any prep blanks
  - Use the drop down tab under **sample type** and select the corresponding option.

10.5.2.5 Copy and paste the CCV & CCB every 10 samples.
- Make sure the correct rack placement is also copied.
- The closing CCV & CCB should also include the closing CRA.

10.5.2.6 Save worksheet before hitting **Go** to begin the analysis.

10.5.3. Saving and Exporting Analytical Run

10.5.3.1 Go to **print preview**. Click the print icon, select **print to file**, select the search box next to **where,** go to the **RawDataPDF** folder, name file the same as analytical run, and save.

NOTE: hit "close" not "X", "X" will close the program.

10.5.3.2 Go to "File" → "Export" → the "HGZ" folder → Name file the same as the analytical run → save.

- Once file is exported, "export complete" will appear.

10.5.4. Post Analytical Run

10.5.4.1 Disconnect the gas line from the GLS.

10.5.4.2 Place Stannous Chloride line into 10% HNO3 solution and allow the instrument to rinse for a few minutes.

10.5.4.3 Place Stannous Chloride line into DI water and allow instrument to rinse for a few minutes.

10.5.4.4 Go to the **Instrument Control/Maintenance Log**, click on the **Autosampler** tab, and under **move sample probe**, select **up.**

10.5.4.5 Place rinse line and Stannous Chloride line into empty beaker.

10.5.4.6 Once the post in the GLS is dry (white in color), turn off both pumps, unclamp the tubes, loosen the tension, and close the program.

10.5.5 The instrument software performs a linear regression analysis of the calibration standards by plotting maximum response of the standards vs. ug of mercury. Mercury concentration in the samples and QC are calculated by comparing response to the calibration curve plot. A linear correlation coefficient of $\geq$0.995 is required for an acceptable calibration curve. The instrument will not proceed with analysis if the curve does not meet this criterion.

10.5.6 All measurements must fall within the defined calibration range to be valid. When sample concentrations exceed the upper limit of the calibration curve, the samples will be diluted and reanalyzed to bring them within the calibration range. When reported sample concentrations either exceed the upper limit of the curve, and the sample cannot be rerun, an NCM will be written and the result will be qualified in the report.

10.5.7 If the sample results are negative and the absolute value of the negative result is greater than the reporting limit, the sample must be diluted and reanalyzed.

10.5.8 Baseline correction is acceptable as long as it is performed after every sample or after the CCV and CCB; resloping is acceptable as long as it is immediately preceded and followed by a compliant CCV and CCB.

10.5.9 The following example run sequence is recommended:

Instrument Calibration
ICV
ICB
RLV or CRA
CCV
CCB
10 samples
CCV
CCB
Repeat sequence of 10 samples between CCV/CCB pairs as required to complete run.
CCV
CCB

10.5.10 For TCLP samples, full four point MSA is required if all of the following conditions are met:

1) recovery of the analyte in the matrix spike is < 50%,
2) the concentration of the analyte does not exceed the regulatory level, and,
3) the concentration of the analyte is within 20% of the regulatory level.

- An alternative to performing MSA is to re-digest and reanalyze the affected sample. If the above criteria are not repeated in the reanalysis, then MSA is not required and reanalysis results shall be reported.
- Appendix A provides guidance on performing MSA analyses. For TCLP mercury determinations, MSA spikes must be added prior to sample preparation.

10.6 To facilitate the early identification of QC failures and samples requiring rerun it is strongly recommended that sample data be reviewed periodically throughout the run.

10.7 Guidelines are provided in the appendices on procedures to minimize contamination of samples and standards, preventive maintenance and parts maintenance. For instrument troubleshooting, use the auto diagnostics software. If the problem cannot be determined using the software, place a call to service personnel.

10.8 One time procedural variations are allowed only if deemed necessary in the professional judgment of supervision to accommodate variation in sample matrix, radioactivity, chemistry, sample size, or other parameters. Any variation in procedure shall be completely documented using a Nonconformance Memo and is approved by a Technical Specialist and

QA Manager. If contractually required, the client shall be notified. The Nonconformance Memo shall be filed in the project file.

10.9 Any unauthorized deviations from this procedure must also be documented as a nonconformance, with a cause and corrective action described.

11 DATA ANALYSIS AND CALCULATIONS

11.1 ICV percent recoveries are calculated according to the equation:

$$\%R = 100\left(\frac{Found(ICV)}{True(ICV)}\right)$$

11.2 CCV percent recoveries are calculated according to the equation:

$$\%R = 100\left(\frac{Found(CCV)}{True(CCV)}\right)$$

11.3 RLV percent recoveries are calculated using the same equation as the ICV or CCV (replace ICV or CCV with RLV in the above equations).

11.4 Matrix spike recoveries are calculated according to the following equation:

$$\%\ R\ = 100\left(\frac{SSR - SR}{SA}\right)$$

Where:

SSR = Spike Sample Result

SR = Sample Result

SA = Spike Added

11.5 The relative percent difference (RPD) of matrix spike/matrix spike duplicates or sample duplicates are calculated according to the following equations:

$$RPD = 100\left[\frac{|MSD - MS|}{\left(\frac{MSD + MS}{2}\right)}\right]$$

Where:

MS = determined spiked sample concentration

MSD = determined matrix spike duplicate concentration

$$RPD = 100\left[\frac{|DU1 - DU2|}{\left(\frac{DU1 + DU2}{2}\right)}\right]$$

Where:

DU1 = Sample result

DU2 = Sample duplicate result

11.6 The final concentration for an aqueous sample is calculated as follows:

mg/L = C x D

Where:

C = Concentration (mg/L) from instrument readout

D = Instrument dilution factor

11.7 For automated determinations, the final concentration determined in solid samples when reported on a dry weight basis is calculated as follows:

mg/kg, dry weight = (C x V x D)/(W x S)

Where:

C = Concentration (ug/L) from instrument readout
V = Volume of digestate (L)
D = Instrument dilution factor
W = Weight in g of wet sample digested
S = Percent solids/100

Note: A Percent Solids determination must be performed on a separate aliquot when dry weight concentrations are to be reported. If the results are to be reported on a wet weight basis, the “S” factor should be omitted from the above equation.

11.8 For automated determinations, the final concentration determined in wipe samples is calculated as follows:

ug/wipe = (C x V x D)

Where:

C = Concentration (ug/L) from instrument readout
V = Volume of digestate (L)
D = Instrument dilution factor

11.8 The LCS percent recovery is calculated according to the following equation:

$$\%R = 100\left(\frac{Found(LCS)}{True(LCS)}\right)$$

11.9 Appropriate factors must be applied to sample values if dilutions are performed.

11.10 Sample results should be reported with up to three significant figures in accordance with the TestAmerica significant figure policy.

12 METHOD PERFORMANCE

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2 Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3 Method Detection Limit Study – A Method Detection Limit (MDL) study, as described in Detection Limit SOP, PT-QA-007, must be performed initially and whenever a significant change is made to the analytical system. The MDL must be re-evaluated from quarterly MDL points at least every 12 months.

12.4 Linear Dynamic Range Verification - The linear range is the concentration above which results cannot be reported without dilution of the sample. The standards used to define the linear range limit must be analyzed under routine analytical conditions. LDRs are instrument specific and must be determined on each instrument annually, or whenever an instrument is adjusted in any way that would affect the range.

12.4.1 For the determination/verification of the upper limit of the linear dynamic range (LDR), determine the signal responses from a minimum of three different concentration standards across the estimated upper range. At least one standard must be above the current highest calibration standard concentration. The determined concentration of the linear range verification standards must be within 10% of the true value. The upper limit of the LDR is set at 90% of the concentration of the highest standard that meets the ±10% recovery limit.

13 POLLUTION PREVENTION

13.1 It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2 This method allows for the proportional reduction of sample and reagent volumes to decrease waste generation.

14 WASTE MANAGEMENT

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.1.1 Extracted sample containing less than 1 ppb Hg. This waste is collected in waste containers identified as "Acid Waste", Waste #33. It is neutralized to a pH between 6 and 9 and is disposed down a lab sink.

14.1.2 Unused Standards. This waste collected in containers identified as "Mercury Standards Waste", Waste #4.

14.1.3 Extracted sample containing greater than 1 ppb Hg. This waste collected in containers identified as "Mercury Standards Waste", Waste #4.

14.1.4 Mercury Analyzer Waste. Waste discharged from mercury analyzer is collected in containers identified as "Mercury Standards Waste", Waste #4.

16 METHOD MODIFICATIONS

16.1 Modifications from 7470A and 245.1

16.1.1 The 200 series methods and Chapter 1 of SW846 specify the use of reagent water with a purity equivalent to ASTM Type II water. This SOP specifies the use of a Millipore DI system or equivalent to produce reagent water. This SOP requires that reagent water must be free of the analytes of interest as demonstrated through the analysis of method blanks.

16.1.2 This SOP allows for the use of reduced sample volumes to decrease waste generation. Reagent levels are adjusted to maintain the same ratios as stated in the source methods. According to a letter from Robert Booth of EPA EMSL-Cincinnati to David Payne of EPA Region V, "Reduction in sample size and appropriate corresponding reduction in sample volume is not considered a significant change in the methodology."

16.1.3 The alternate run sequence presented in Section 10.3.7 is consistent with method requirements.

16.2 Modifications from Methods 7470A/7471B

16.2.1 Chapter 1 of SW-846 states that the method blank should not contain any analyte of interest at or above the MDL. This SOP states that the method blank must not contain any analyte of interest at or above the reporting limit.

16.2.2 Chapter 1 of SW846 specifies the use of reagent water with a purity equivalent to ASTM Type II water. This SOP specifies the use of a Millipore DI system or equivalent to produce reagent water. This SOP requires that reagent water must be free of the analytes of interest as demonstrated through the analysis of method blanks.

16.3 Modifications from 245.1

16.3.1 Method 245.1, Section 9.3 states concentrations should be reported as follows: Between 1 and 10 ug/L, one decimal; above 10 ug/L, to the nearest whole number. TestAmerica reports all Hg results under this SOP to two significant figures.

16.4 Modifications from SW846 7471A/B

16.4.1 A potassium persulfate oxidation step has been included to facilitate the breakdown of organic mercurials which are not completely oxidized by potassium permanganate. Use of potassium persulfate in combination with the permanganate improves the recovery of mercury from organo-mercury compounds. The use of persulfate has been incorporated in several recent EPA mercury protocols.

16.5 Autoblock digestion is performed with proportional reduction of samples, standards, and all reagent volumes.

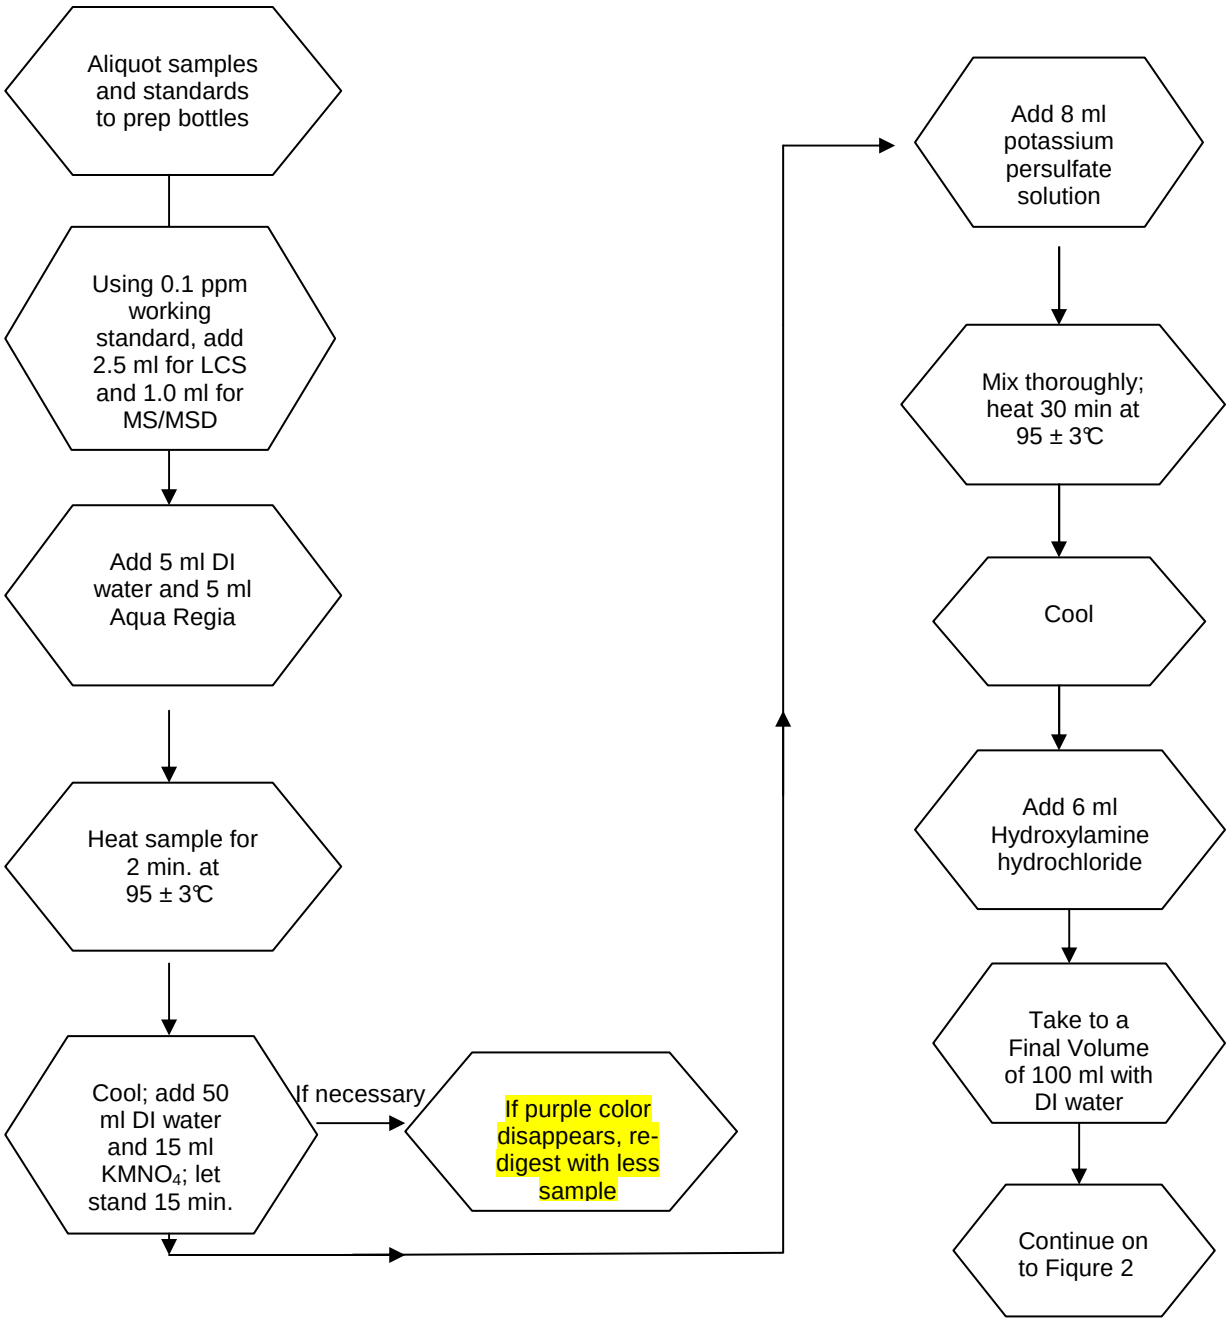

Figure 3 – CVAA Instrumental Analysis Flowchart

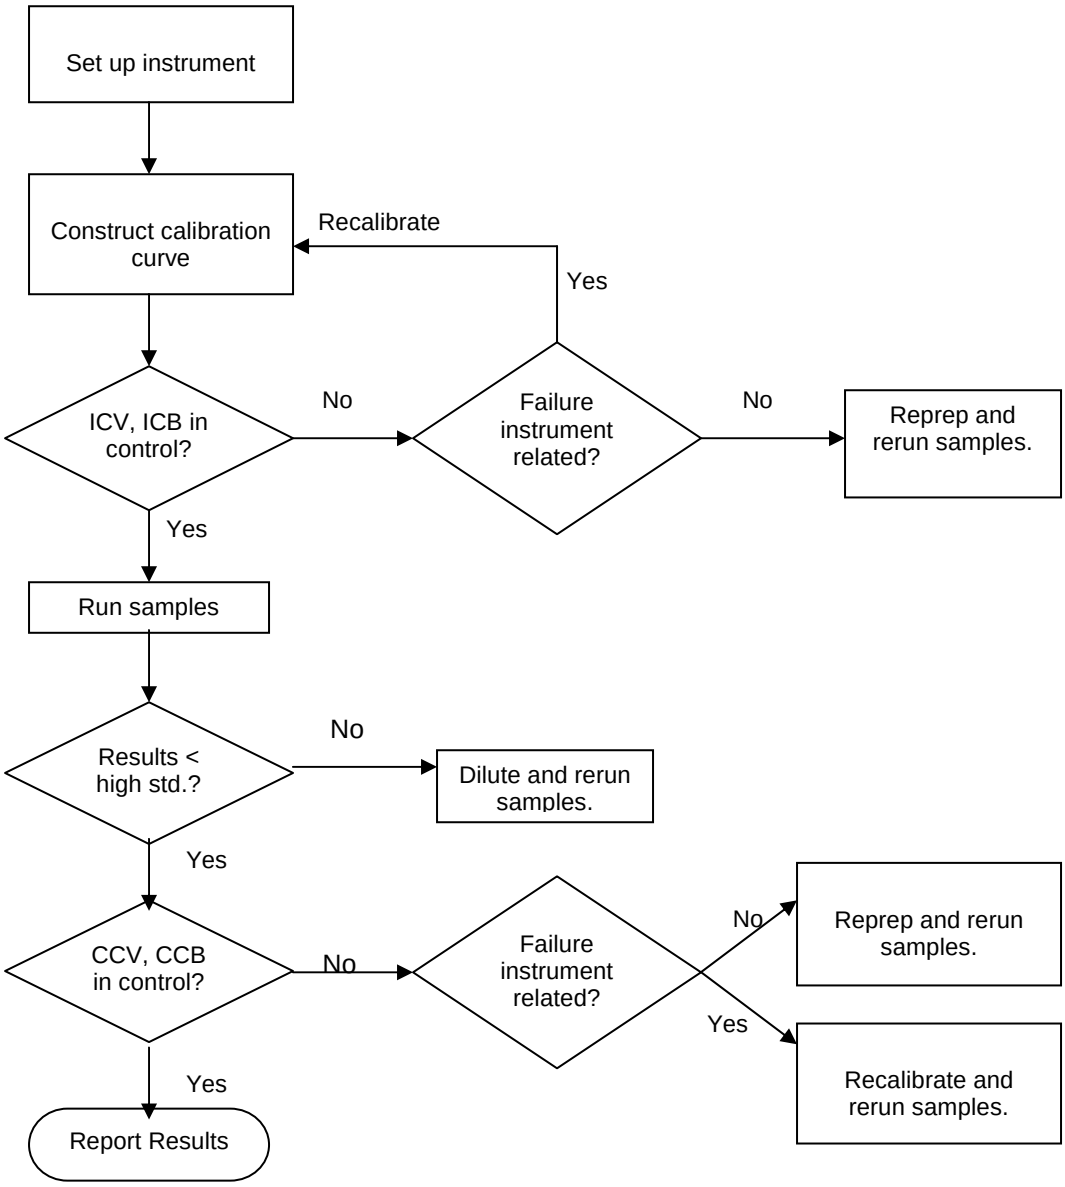

TABLE 1

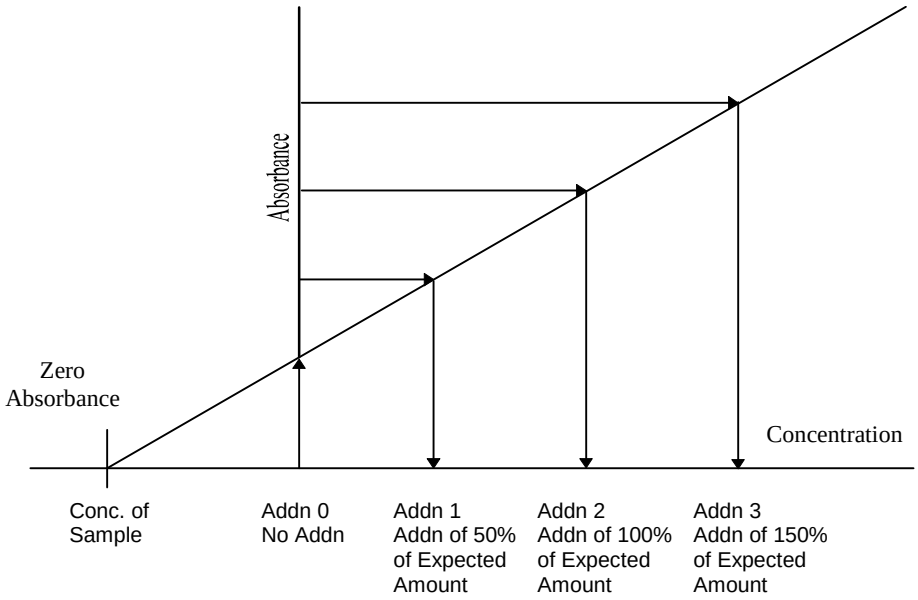
CALIBRATION STANDARD*, QC STANDARD AND SPIKING LEVELS (MG/L)

Standard or QC	mL of 0.10 ppm Working Standard for manual digestion (50mL)	Final Volume (mL)	Concentration (mg/L)
Std 0	0	100	0
Std 1	0.20	100	0.0002
Std 2	0.50	100	0.0005
Std 3	1.0	100	0.001
Std 4	5.0	100	0.005
Std 5	10	100	0.010
ICV	2.5**	100	0.0025
CCV	5.0	100	0.005
RLV/CRA	0.20	100	0.0002
LCS (manual)	1.25	50	0.0025
LCS (Autoblock)	0.625	25	0.0025
MS (manual)	0.50	50	0.001
MS (Autoblock)	0.25	25	0.001
TCLP MS (manual)	0.25	50	0.005
TCLP MS (Autoblock)	0.125	25	0.005

SOP specified calibration levels must be used unless prevented by the instrument configuration or client specific requirements.

** Prepared from a second source 0.1 ppm working standard.

NOTE: TCLP initial sample volume is 5mL for manual digestion and 2.5mL for Autoblock digestion



APPENDIX A - MSA GUIDANCE

Method of Standard Addition

Four equal volume aliquots of sample are measured and known amounts of standards are added to three aliquots. The fourth aliquot is the unknown and no standard is added to it. The concentration of standard added to the first aliquot should be 50% of the expected concentration. The concentration of standard added to the second aliquot should be 100% of the expected concentration and the concentration of standard added to the third aliquot should be 150% of the expected concentration. The volume of the unspiked and spiked aliquots should be the same (i.e., the volume of the spike added should be negligible in relation to the volume of sample).

To determine the concentration of analyte in the sample, the absorbance (or response) of each solution is determined and a linear regression performed. On the vertical axis the absorbance (or response) is plotted versus the concentrations of the standards on the horizontal axis using 0 as the concentration of the unspiked aliquot. An example plot is shown in Figure 1. When the resulting line is extrapolated back to zero absorbance, the point of interception of the horizontal axis is the concentration of the unknown. Calculate the correlation coefficient (r) and the x-intercept (where y=0) of the curve. The concentration in the digestate is equal to the negative x-intercept.

Figure 1

- For the method of standard additions to be correctly applied, the following limitations must be taken into consideration.
- The plot of the sample and standards must be linear over the concentration range of concern. For best results, the slope of the curve should be similar to that of a plot of the aqueous standard curve.
- The effect of the interference should not vary as the ratio of the standard added to the sample matrix changes.

APPENDIX B - MAINTENANCE GUIDE

Cold Vapor Atomic Absorption Mercury Instrument Maintenance Schedule

Daily	As Needed	Annually
Check aperture reading.	Check Hg lamp intensity.	Change Hg lamp every 50,000 hours of operation
Check argon flow/pressure.	Clean optical cell	Check liquid/gas separator.
Check tubing and replace every 50 hours of operation.	Lubricate pump	
Check drain.	Clean lens windows with methanol.	
	Replace drying tube every 300 hours of operation	
	Change permanganate trap every 1000 hours of operation	

APPENDIX C - CONTAMINATION CONTROL GUIDELINES

The following procedures are strongly recommended to prevent contamination:

All work areas used to prepare standards and spikes should be cleaned before and after each use.

All glassware should be washed with detergent and tap water and rinsed with 20% nitric acid followed by deionized water.

Proper laboratory housekeeping is essential in the reduction of contamination in the metals laboratory. All work areas must be kept scrupulously clean.

Powdered or Latex Gloves must not be used in the metals laboratory since the powder contains silica and zinc, as well as other metallic analytes. Only vinyl or nitrile gloves should be used in the metals laboratory.

Glassware should be periodically checked for cracks and etches and discarded if found. Etched glassware can cause cross contamination of any metallic analytes.

Autosampler trays should be covered to reduce the possibility of contamination. Trace levels of elements being analyzed in the samples can be easily contaminated by dust particles in the laboratory.

The following are helpful hints in the identification of the source of contaminants:

Reagents or standards can contain contaminants or be contaminated with the improper use of a pipette.

Improper cleaning of glassware can cause contamination.

Separate glassware if an unusually high sample is analyzed and soak with sulfuric acid prior to routine cleaning.

APPENDIX D - PREVENTIVE MAINTENANCE

A maintenance log is used to record when maintenance is performed on instruments. When an instrument problem occurs indicate the date, time and instrument number, then identify the problem and corrective action in the maintenance log.

The following procedures are required to ensure that that the instrument is fully operational.

Cold Vapor Atomic Absorption (Hydra AA)

Daily	As Needed	Annually
Check Hg lamp intensity.	Clean lens windows with methanol.	Change Hg lamp.
Check aperture reading.	Clean optical cell	Check liquid/gas separator.
Check pump tubing/drain tubing.	Lubricate pump	
Check argon flow/pressure.		
Check tubing and replace, if needed.		
Check drain.		
Replace drying tube.

1.0 SCOPE AND APPLICATION

1.1 This SOP describes extraction procedures for the preparation of semivolatile organic analytes in aqueous and TCLP leachate matrices for analysis by Gas Chromatography (GC) and Gas Chromatography / Mass Spectrometry (GC/MS). The procedures are based on SW-846 and 600 series methodology and are applicable for measurements made to comply with the Resource Conservation and Recovery Act (RCRA) and for wastewater testing.

1.2 Extraction procedures 608/608.3, 625/625.1, 3510C, and 3520C for the following determinative methods are covered: 608, 608.3, 625, 625.1, 8081A, 8081B, 8082, 8082A 8141A, 8141B, 8270C, 8270D, and 8270E.

NOTE: Some, but not all, methods are available for the Low Volume Initiative (LVI) extraction with proportionally reduced volumes to reduce waste.

1.3 The extraction procedures discussed here may be appropriate for other determinative methods when appropriate spiking mixtures are used.

1.4 On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department or the Laboratory or Technical Director and documented fully in an NCM that accompanies the analytical batch.

1.5 Different levels of concentration and volumes are available to meet client specific needs. Regular level analyses are normally performed on 1 liter initial sample volumes. Low-level analyses are concentrated to a smaller final volume and offer reporting limits that are 10-40 times lower than the regular level analysis. Low Volume Initiative (LVI) extractions are performed on 100 to 250mL initial sample volumes with proportional reduction of reagents, spikes and final volumes. See Table 2 for initial and final volume details. LVI extraction procedures are performed with initial volumes of 250 mL.

NOTE: LVI extractions are not to be used for samples from South Carolina.

2.0 SUMMARY OF METHOD

2.1 Separatory Funnel Extraction

A measured volume of sample, typically 1 liter (250 mL for LVI), is adjusted, if necessary, to a specified pH and serially extracted with methylene chloride using a separatory funnel.

2.2 Continuous Liquid/Liquid Extraction (CLLE)

A measured volume of sample, typically 1 liter (250 mL for LVI), is placed into a continuous liquid/liquid extractor, adjusted, if necessary, to a specific pH and extracted with methylene chloride for 18-24 hours.

2.3 Concentration

Extracts are concentrated to specific final volumes by evaporation of the solvent under controlled conditions.

3.0 DEFINITIONS

3.1 Definitions of terms used in this SOP may be found in the glossary of the Pittsburgh Quality Assurance Manual (PT-QA-M-001).

3.2 TALS – TestAmerica Laboratory Information Management System

3.3 NCM – Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

4.0 INTERFERENCES

4.1 Method interferences may be caused by contaminants in solvents, reagents, glassware, and other processing apparatus. All these materials must be routinely demonstrated to be free from interferences under conditions of the analysis by running laboratory method blanks as described in the Quality Control section. Specific selection of reagents may be required to avoid introduction of contaminants.

4.2 Visual interferences or anomalies (such as foaming, emulsions, odor, etc.) must be documented.

4.3 Residual Chlorine from water treatment must be removed from samples prior to extraction for 625 analysis and for 608 analysis when Aldrin is included in the compound list.

5.0 SAFETY

5.1 Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001), and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2 Samples containing or suspected to contain cyanide or sulfide concentrations at or greater than 250 ppm or 500 ppm, respectively, shall be processed in a fume hood.

5.3 The use of separatory funnels to extract aqueous samples with Methylene Chloride creates excessive pressure very rapidly. Initial venting should be done immediately after the sample container has been sealed and inverted. Vent the funnel into the hood away from people and other samples. This is considered a high-risk activity, and a face shield must be worn over safety glasses or goggles when it is performed.

5.4 Nitrile gloves should be used when performing this extraction. Latex and vinyl gloves provide no significant protection against the organic solvents used in this SOP, and should not be used.

5.5 During Kuderna-Danish (KD) concentration, do not allow the extract to boil to dryness. The solvent vapors remaining in the KD apparatus may superheat and create an explosion or fire hazard. The KD apparatus and glass separatory funnels have ground glass joints, which can become stuck. Technicians must use Kevlar or other cut/puncture resistant gloves when separating stuck joints.

5.6 Care must be used when separating glass parts of extraction and concentration setups. Protective gloves must be used when separating stuck glass joints.

5.7 The following is a list of the materials used in this method, which have a serious or significant hazard rating. NOTE: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material	Hazards	Exposure Limit[i]	Signs and symptoms of exposure
Acetone	Flammable	1000 ppm-TWA	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Hexane	Flammable Irritant	500 ppm-TWA	Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Vapors may cause irritation to the skin and eyes.
Methylene Chloride	Carcinogen Irritant	25 ppm-TWA 125 ppm-STEL	Causes irritation to respiratory tract. Has a strong narcotic effect with symptoms of mental confusion, light-headedness, fatigue, nausea, vomiting and headache. Causes irritation, redness and pain to the skin and eyes. Prolonged contact can cause burns. Liquid degreases the skin. May be absorbed through skin.
Sodium Hydroxide	Corrosive Poison	2 ppm, 5 mg/m^3	This material will cause burns if comes into contact with the skin or eyes. Inhalation of Sodium Hydroxide dust will cause irritation of the nasal and respiratory system.
Sulfuric Acid[ii]	Corrosive Oxidizer Dehydrator	1 mg/m^3	This material will cause burns if comes into contact with the skin or eyes. Inhalation of vapors will cause irritation of the nasal and respiratory system.

[i] Exposure limit refers to the OSHA regulatory exposure limit.
[ii] Always add acid to water to prevent violent reactions.

5.8 Eye protection that protects against splash, laboratory coat and appropriate gloves must be worn while samples, standards, solvents and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have become contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.9 The preparation of standards and reagents and glassware cleaning procedures that involve solvents such as methylene chloride will be conducted in a fume hood with the sash closed as far as the operations will permit. Use of methylene chloride for glassware cleaning should be avoided as far as possible.

5.10 All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

6.0 EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 Glassware should be cleaned with soap and water, rinsed with water and dried in an oven at 400°C for at least 2 hours. Alternatively the glassware can be solvent rinsed with acetone or methanol followed by methylene chloride after the water rinse.

6.2 Equipment and supplies for extraction procedures

EQUIPMENT AND SUPPLIES	Separatory funnel	CLLE	Conc
Separatory Funnel: 2 L, 500 mL	X		
Separatory Funnel Rack	X		
Balance: >1400 g capacity, accurate ±1 g	X	X	
pH indicator paper, wide-range: covers extraction pH	X	X	
Graduated cylinder: 1 liter. (other sizes may be used)	X	X	
Erlenmeyer Flask or Fleaker: 125 & 300 mL (other sizes optional)	X		
Solvent Dispenser Pump or 100 mL Graduated Cylinder	X		
Continuous Liquid/Liquid Extractor		X	
Round or flat Bottom: 250, 500 mL or 1 L		X	
Boiling Chips: Contaminant free, approximately 10/40 mesh (Teflon® PTFE, carbide or equivalent).		X	X
Cooling Condensers		X	
Heating Mantle: Rheostat controlled		X	
Auto-timer for heating mantle		X	
Kuderna-Danish (K-D) Apparatus: 500 mL, 250 mL			X
Concentrator Tube: 10 mL, attached to K-D with clips			X
Snyder Column: Three-ball macro			X

EQUIPMENT AND SUPPLIES	Separatory funnel	CLLE	Conc
Water Bath: Heated, with concentric ring cover, capable of temperature control (± 5°C) up to 95°C. The bath must be used in a hood or with a solvent recovery system.			X
Vials: Glass, 2 mL, 4 mL, and 10 mL capacity with Teflon®-lined screw-cap			X
Nitrogen Blowdown Apparatus			X
Nitrogen: reagent grade.			X
Culture tubes: 10 mL, 16 mmx100 mm			X
Syringe: 1 mL	X	X	
Phase Separation Paper	X	X	
Glass Wool	X	X	
Glass Funnel: 75 X 75 mm	X	X	X
Disposable Pipettes	X	X	X
Potassium Iodide-Starch Indicator Paper	X	X	
Aluminum foil	X	X	X
Paper Towels	X	X	X

7.0 REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the MSDS prior to the use of any reagent or standard.

7.1 Reagents for Extraction Procedures

All reagents must be ACS reagent grade or better unless otherwise specified.

REAGENTS	Separatory funnel	CLLE	Conc.
Sodium hydroxide (NaOH), Pellets: Reagent Grade	X	X	
Sodium hydroxide solution, 10 N: Dissolve 40 g of NaOH in reagent water and dilute to 100 mL.	X	X	
Sulfuric acid (H_2SO_4), Concentrated: Reagent Grade	X	X	
Sulfuric acid (1:1): Carefully add 500 mL of H_2SO_4 to 500 mL of reagent water. Mix well.	X	X	
Organic free reagent water.	X	X	
Sodium sulfate (Na_2SO_4), Granular, Anhydrous: Purify by heating at 400°C a minimum of four hours.	X	X	
Extraction/Exchange Solvents: Methylene chloride, hexane, acetone, pesticide quality or equivalent	X	X	X
Acetone: Used for cleaning	X	X	X
Sodium Thiosulfate, granular	X	X	

7.2 Standards

7.2.1 Stock Standards

Stock standards are purchased as certified solutions or prepared from neat. Semivolatile stock standards are stored at > 0.0ºC but ≤ 6.0ºC. All

stock standards must be protected from light. Stock standard solutions must be replaced after one year (from the time of preparation, if prepared in house, or from the time the ampule is opened if purchased.) Standards must be allowed to come to room temperature before use.

7.2.2 Surrogate Spiking Standards

Prepare or purchase surrogate spiking standards at the concentrations listed in Work Instruction PT-OP-WI-001. Surrogate spiking standards are prepared as dilutions of the stock standards in methanol or other water miscible solvent. Surrogate spiking solutions must be refrigerated and protected from light. The standards must be replaced at least every six months or sooner if there is reason to believe that the standard has degraded or concentrated.

7.2.3 Matrix Spiking and Laboratory Control Spiking Standards

The same spiking solution is used for the matrix spike and the Laboratory Control Sample. Prepare MS/LCS spiking standards at the concentrations listed in Work Instruction PT-OP-WI-001. Spiking standards are purchased or prepared as dilutions of the stock standards in methanol or other water miscible solvent. Spiking solutions must be refrigerated and protected from light. The standards must be replaced at least every six months or sooner if there is reason to believe that the standard has degraded or concentrated.

8.0 SAMPLE COLLECTION PRESERVATION, SHIPMENT AND STORAGE

Matrix	Sample Container	Min. Sample Size	Preservation	Leachate Extraction Holding Time	Extraction Holding Time
Waters	1 liter amber	1 Liter	Cool, > 0.0ºC but ≤ 6.0ºC	NA	7 Days
LVI Waters	250 mL amber	250 mL	Cool, > 0.0ºC but ≤ 6.0ºC	NA	7 Days
Waters for PCB Analysis (608 or 8082)	1 liter amber	1 Liter	Cool, > 0.0ºC but ≤ 6.0ºC	NA	1 year
Leachates	4oz Jar	100 grams	Cool, > 0.0ºC but ≤ 6.0ºC	14 Days	7 Days

9.0 QUALITY CONTROL

9.1 Extraction batches are composed of twenty or fewer samples, of similar matrix, plus the required batch QC. Laboratory generated QC samples (method blanks, LCS, MS/MSD) are not included in the sample count.

9.2 If insufficient sample is available to process a MS/MSD, then an LCS Duplicate may be processed to evaluate batch extraction precision. Use of a LCS/LCSD

pair in place of a MS/MSD due to insufficient sample volume must be documented using the "Insufficient Volume" NCM. Because subsamples cannot be taken from a wipe sample for MS/MSD analyses, wipe samples should be processed with a LCS/LCSD.

9.3 The extraction of at least a Matrix Spike is required for all methods. If double sample volume is not provided for any samples in the batch, document this with the "Insufficient Volume" NCM.

9.4 The following quality control samples are prepared with each batch of samples. For QC control limits, refer to the individual analytical method SOPs and TALS.

Quality Controls	Frequency
Method Blank (MB)	1 per preparation batch[1]
Laboratory Control Sample (LCS)	1 per preparation batch[1]
Matrix Spike (MS)[2,3]	1 per preparation batch[1]
Matrix Spike Duplicate (MSD)[2,3]	1 per preparation batch[1]
Surrogates	All samples and QC

[1]A preparation batch is limited to 20 samples, except for 608 and a batch is limited 10 samples.
[2]The sample used for MS/MSD is randomly selected, unless specifically requested by a client.
[3]An MS should be performed without an MSD if there is insufficient volume for both.

9.5 Method Blank

A method blank with all reagents added the same as to the samples must be prepared and analyzed with each batch of samples. Surrogates are spiked into the method blank at the same level as the samples. The method blank is used to identify any background interference or contamination of the analytical system, which may lead to the reporting of elevated concentration levels or false positive data.

9.5.1 Aqueous Method Blanks use 1000 mL (250 mL for LVI batches) of reagent water spiked with the surrogates. The method blank goes through the entire analytical procedure, including any cleanup steps.

9.5.2 TCLP Leachate Blanks (LB) use 200 mL of leachate fluid for GC/MS Semivolatiles and 100 mL for organochlorine pesticides. The leachate blank may optionally be diluted to 1000 mL with reagent water. Once the organic prep group receives the TCLP samples and leachate blank they will extract all using the appropriate method and QC, including an extracted method blank. The method blank and leachate blank go through the entire analytical procedure, including any cleanup steps.

9.6 Laboratory Control Sample (LCS)

Laboratory Control Samples are clean matrix, known concentration, laboratory-generated samples used to monitor the laboratory's day-to-day performance of routine analytical methods. The LCS, spiked with the list of target compounds

representative of the method analytes, is used to monitor the accuracy of the analytical process, independent of matrix effects. On-going monitoring of the LCS results provides evidence that the laboratory is performing the method within accepted QC guidelines for accuracy and precision. The LCS goes through the entire analytical procedure, including any cleanup steps.

9.6.1 The LCS is made up in the same way as the method blank (See sections 9.5.1 - 9.5.2) but spiked with the LCS standard as well as the surrogates.

9.6.2 For the 600 series methods (608 and 625), the LCS is equivalent to the QC Check Sample specified in the reference methods.

9.7 Surrogates

9.7.1 Surrogates are organic compounds which are similar to the target analyte(s) in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.

9.7.2 Each sample, blank, LCS and MS/MSD is spiked with surrogate standards prior to the extraction process. Surrogate spike recoveries must be evaluated by determining whether the concentration (measured as percent recovery) falls within the required recovery limits.

9.8 Matrix Spike/Matrix Spike Duplicate (MS/MSD)

9.8.1 A matrix spike is an environmental sample to which known concentrations of target analytes have been added. A matrix spike duplicate is a second spiked aliquot of the same sample, which is spiked prior to the beginning of the extraction process and prepared and analyzed along with the sample and matrix spike. Matrix spike analysis is required for every 20 samples, except for method 608, which is every 10 samples.

9.8.2 If sufficient volume is not received for both and MS and MSD, at least an MS should be extracted along with the batch to meet method QC requirements.

10.0 PROCEDURE

Procedures for separatory funnel liquid/liquid extraction (10.1), continuous liquid/liquid extraction (10.2), and extract concentration (10.3) are presented in this section.

10.1 Separatory Funnel Liquid/Liquid Extraction of Water Samples:

Refer to Figure 1 – Separatory Funnel Extraction flowchart.

10.1.1 Remove surrogate and matrix spiking solutions from refrigerator and allow them to warm to room temperature.

10.1.2 Mark the meniscus of the sample volume on the sample bottle.

10.1.3 For 625 samples, and 608 samples when the compound list includes Aldrin, check samples for residual chlorine by adding a few drops of

sample from a pipette or glass stirring rod onto a piece of potassium iodide (KI) - starch paper that has been moistened with reagent water.

10.1.3.1 If the paper turns blue, treat the entire sample volume by adding a small scoop of granular sodium thiosulfate. Check the sample again with KI-starch paper. Continue treating and checking the sample until the paper no longer turns blue.

10.1.3.2 If the residual chlorine cannot be removed after 4 additions of sodium thiosulfate, contact the PM to obtain the client's instructions on whether to proceed with the extraction.

10.1.3.3 Document any samples that have been treated to remove residual chlorine using the "Residual Chlorine" NCM.

10.1.4 Spike all samples in the bottle with surrogate solution. Also spike the MS and MSD aliquots with Matrix Spike solution (Refer to Work Instruction PT-OP-WI-001). Replace the cap and mix well. Record the spike volumes and standard numbers on the TALS worksheet. Return spiking solutions to the refrigerator as soon as possible.

Note: If the sample bottle is completely full, it may be difficult to add the spike solutions to the bottle. In this case, transfer the sample to the separatory funnel and then add the spike prior to adding any methylene chloride.

10.1.5 Measure the initial sample pH with wide-range pH paper and record on the TALS worksheet. If sample is a leachate (e.g. TCLP), compare the current pH against leachate log, Note on the benchsheet if there is any discrepancy.

10.1.5.1 Refer to Table 1 for the required extraction pH for each method. If required, sample pH is adjusted in the sample bottle if possible, to the pH range as indicated in Table 1. Use the minimum amount of 1:1 H_2SO_4 or 10 N NaOH necessary to adjust the pH into the required range. Recheck the sample with pH paper by dipping a disposable pipette into the sample and wetting the pH paper. Record the adjusted pH on the TALS worksheet.

Note: If the sample bottle is completely full, it may be difficult to adjust the pH in the bottle. In this case, transfer the sample to the separatory funnel and then adjust the pH prior to adding any methylene chloride.

10.1.5.2

10.1.6 The normal sample volume is approximately 1 liter (250 mL for LVI). Clients may send bottles that have not been completely filled. The entire volume in the bottle is extracted, and the exact volume used is documented in the TALS batch.

10.1.6.1 Other sample volumes may be used to obtain specific reporting limits, and reduced sample volumes, diluted to 1 liter with

reagent water, may be used for very dirty samples. Unusual volumes, other than LVI, must be documented in an NCM.

10.1.7 Transfer the entire sample to the separatory funnel. Add 60 mL of methylene chloride to the bottle. Cap and shake for approximately 30 seconds to rinse all inner surfaces. Transfer the methylene chloride to the separatory funnel.

10.1.8 The sample volume is determined by filling the sample bottle with reagent water up to the marked meniscus or to the top of the sample bottle if the bottle is completely full and measuring that volume in a graduated cylinder. Record the volume to the nearest 10 mLs.

10.1.8.1 If the entire sample bottle will not be used (i.e., for smaller sample aliquots such as TCLP), mix the sample in the bottle and measure out the desired volume in a graduated cylinder. Spike the surrogate, and MS solution, where appropriate, and adjust initial sample pH in the cylinder. Transfer the aliquot to the separatory funnel.

10.1.8.2 Rinse the cylinder with 60 mL (15 mL for LVI) of methylene chloride and transfer to the separatory funnel.

10.1.9 Prepare a method blank, LCS, MS and MSD for each batch as specified in section 9 of this SOP. The LCS and MS/MSD are spiked with the surrogate and matrix spike solutions, the method blank only with the surrogates (see Work Instruction PT-OP-WI-001 for spike volumes).

10.1.10 Seal and shake or rotate the separatory funnel vigorously for 2 minutes with periodic venting to release excess pressure.

Warning: Methylene chloride creates excessive pressure very rapidly. Therefore, initial venting should be done immediately after the separatory funnel has been sealed and inverted. Vent into hood away from analysts and other samples.

10.1.11 Allow the organic layer to separate from the water phase until complete visible separation has been achieved (approximately 10 minutes). If the emulsion interface between layers is more than one-third the size of the solvent layer, the analyst must employ mechanical techniques to complete the phase separation.

- The optimum technique depends upon the sample and may include stirring, filtration of the emulsion through glass wool, centrifugation, or other physical methods.
- If the emulsion cannot be broken (recovery of <80% of the methylene chloride*), transfer the sample, solvent, and emulsion into the extraction chamber of a continuous liquid-liquid extractor (CLLE) and proceed as described in continuous liquid-liquid extraction (Section 10.2). If this is done, the sample must be extracted as part of a valid CLLE batch, with all associated QC.

Note: 15 - 20 mL of methylene chloride is expected to dissolve in 1 L of water. Thus, solvent recovery could be as low as 35 mL from the first shake and still be acceptable. Subsequent shakes should recover at least 50 mL of solvent.

10.1.12 Fill a funnel with 10-20 g of anhydrous sodium sulfate. The funnel can be plugged with glass wool or filter paper may be used to hold the sodium sulfate. Drain the solvent extract from the separatory funnel through the prepared filtration funnel into a clean glass container. The extract may be drained directly into the KD flask. Close the stopcock just before the water level begins draining out of the separatory funnel. If the sodium sulfate becomes saturated with water add more to the funnel or replace the existing sodium sulfate with fresh drying agent.

10.1.13 Use a second 60 mL (15 mL for LVI) portion of methylene chloride to rinse the bottle and transfer it to the separatory funnel. Repeat the extraction process, filtering the extract through the same filter funnel into the same collection vessel. Repeat the extraction process a third time using a fresh 60 mL portion of solvent. Combine all three solvent extractions in the collection container.

10.1.14 If extraction at a secondary pH is required, adjust the pH of the sample in the separatory funnel to the pH indicated in Table 1 with a minimum amount of 10 N NaOH or 1:1 H_2SO_4. Measure with pH paper and record the adjusted pH on the TALS worksheet. Serially extract with three 60 mL (15 mL for LVI) portions of methylene chloride, as outlined in Steps 10.1.10 to 10.1.12. Collect these three extracts in the same container used for the initial pH fraction.

Note: Alternatively, the acid and base fractions may be kept separate. Separate analysis of the acid and base fractions may be required for method 625. Individual client requirements must be checked before starting the extraction.

10.1.15 Rinse the extract residue from the sodium sulfate by pouring 20-30 mL (5-10mL for LVI) of clean methylene chloride through the funnel and into the collection container.

10.1.16 Dispose of water remaining in the separatory funnel into the appropriate waste container.

10.1.17 Cover the collection container with aluminum foil if the extract is not concentrated immediately. Refer to Section 10.3 for concentration.

10.2 Continuous Liquid/Liquid Extraction from Water Samples:

Refer to Figure 2 – Continuous Liquid/Liquid Extraction flowchart.

10.2.1 Remove surrogate and matrix spiking solutions from refrigerator and allow them to warm to room temperature.

10.2.2 Assemble the apparatus. Add 200-300 mL (100 mL for LVI) of methylene chloride to the extractor body. Add 3 to 5 boiling chips to the round-bottom distilling flask.

10.2.3 Mark the meniscus of the sample volume on the sample bottle.

10.2.4 See section 10.1.3 above for checking and treating residual chlorine in 625 and 608 samples.

10.2.5 Spike all samples in the bottle with surrogate solution. Also spike the MS and MSD aliquots with Matrix Spike solution (see Work Instruction PT-OP-WI-001 for spike volumes). Mix well. Record the spike volumes and standard numbers on the TALS worksheet. Return spiking solutions to the refrigerator as soon as possible.

Note: If the sample bottle is completely full, it may be difficult to add the spike solutions to the bottle. In this case, transfer the sample to the extractor and then add the spike prior to adding any methylene chloride.

10.2.6 Measure the initial sample pH with wide-range pH paper and record on the extraction TALS worksheet. If sample is a leachate (e.g. TCLP), compare the current pH against the leachate log. Note on the benchsheet if there is any discrepancy.

10.2.6.1 Refer to Table 1 for the required extraction pH for each method. If required, sample pH is adjusted in the sample bottle if possible, to the pH range as indicated in Table 1, for the initial extraction. Use the minimum amount of 1:1 H_2SO_4 or 10 N NaOH necessary to adjust the pH into the required range. Recheck the sample with pH paper by dipping a disposable pipette into the sample and wetting the pH paper. Record the adjusted pH on the TALS worksheet.

Note: If the sample bottle is completely full, it may be difficult to adjust the pH in the bottle. In this case, transfer the sample to the extractor and then adjust the pH prior to adding any methylene chloride.

10.2.7 Transfer the entire sample to the liquid-liquid extractor. Add 60 mL (15 mL for LVI) of methylene chloride to the bottle. Cap and shake for approximately 30 seconds to rinse all inner surfaces. Transfer the methylene chloride to the liquid-liquid extractor.

10.2.7.1 Repeat the sample bottle rinse with an additional 50-100 mL (15-20 mL for LVI) portion of methylene chloride and add the rinse to the extractor.

10.2.8 The sample volume is determined by filling the sample bottle with reagent water up to the marked meniscus or to the top of the sample bottle if the bottle is completely full and measuring that volume in a graduated cylinder. Record the volume to the nearest 10 mLs.

10.2.8.1 If the entire sample bottle will not be used (i.e., for smaller sample aliquots such as TCLP), mix the sample in the bottle and

measure out the desired volume in a graduated cylinder. Spike the surrogate, and MS solution, where appropriate, and adjust initial sample pH in the cylinder. Transfer the aliquot to the liquid-liquid extractor.

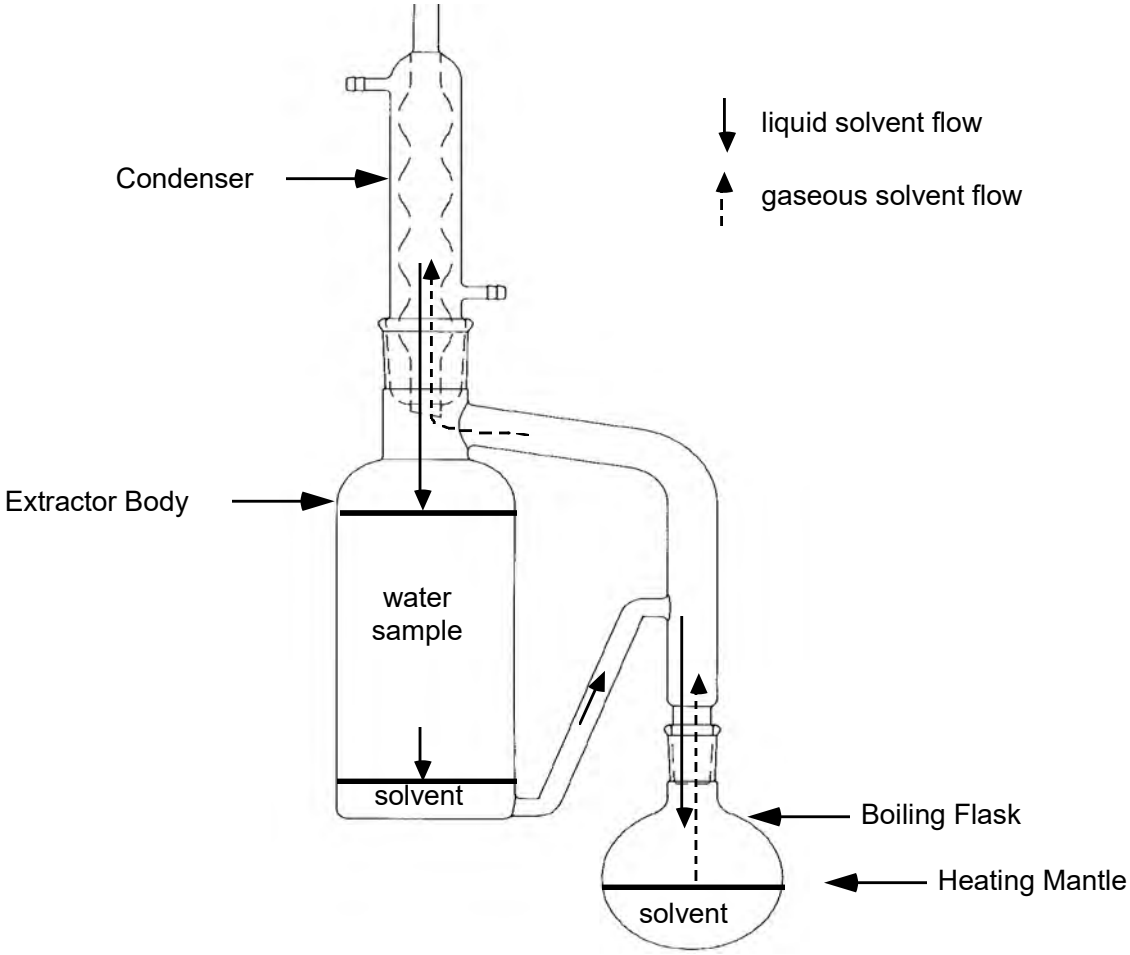
10.2.8.2 Rinse the cylinder with 60 mL (15 mL for LVI) of methylene chloride and transfer to the liquid-liquid extractor.

10.2.9 Prepare a method blank and LCS for each batch as specified in section 9 of this SOP. Use 1 L (250 mL for LVI) of reagent water for method blanks and LCS. The method blank is spiked with the surrogates, the LCS and matrix spikes with the surrogates and matrix spiking solutions. Note that different spiking solutions are used for methods 625, 8270 and TCLP (see Tables 3 and 4 for spike volumes).

10.2.10 Use 200 mL of leachate for TCLP semivolatiles, measured in a graduated cylinder. The leachate may be made up to 1 L in volume with reagent water.

10.2.11 For a TCLP method blank, 200 mL (semivolatiles) of the buffer solution used in the leaching procedure and transfer to the separatory funnel. Dilute to about 1 liter with reagent water.

10.2.12 Add reagent water to the extractor body until approximately 125 mL (35 mL for LVI) of methylene chloride is pushed over into the round-bottomed flask to ensure proper operation and solvent cycling. Attach cold condenser (about 10°C). Turn on heating mantle. Inspect joints for leaks once solvent has begun cycling. Extract for 18-24 hours for both the 3500 and 600 series methods.



- For method 625.1, the sample pH must be checked after 2 hours of the extraction.
  - After 2 hours of extracting, turn the heating off on the samples and allow set-ups to cool for at least 20 minutes.
  - Using a disposable glass pipette, reach down to the water in the extractor body and collect a drop of sample. Drip this onto a strip of pH paper.
  - If the pH of the sample is still within the required range for that step of the extraction, continue the extraction for another 16-22 hours. Record the pH on the extraction worksheet.
  - If the pH of the sample is outside the range required, adjust the pH again to the required range within the extractor, and then continue the extraction for another 16-22 hours. Record both the observed and adjust-to pH's on the extraction worksheet.

10.2.13 If extraction at a secondary pH is required, (see Table 1) turn off the heating mantle and allow the extractor to cool. Detach the condenser and adjust the pH of the sample in the extractor body to the pH indicated in Table 1 with a minimum amount of 10 N NaOH or 1:1 H_2SO_4. Measure with pH paper and record the adjusted pH on the benchsheet. If desired, the acid and base fractions may be kept separate by replacing the boiling

flask with a clean flask and fresh solvent. Reattach the condenser and turn on heating mantle. Extract for 18-24 hours for both the 3500 and 600 series methods.

- For method 625.1, follow the procedure in section 10.2.12 above for checking the pH after 2 hours of extracting.

Note: Alternatively, the acid and base fractions may be kept separate. This may be required for method 625. Separate analysis of the acid and base fractions may also be required for method 625. Individual client requirements must be checked before starting the extraction.

10.2.14 Turn off the heating mantle and allow the extractor to cool.

10.2.15 Place a funnel containing 10-20 g of anhydrous sodium sulfate on the Kuderna-Danish (K-D) apparatus or other glass container. The funnel can be plugged with glass wool enabling it to hold the granular anhydrous sodium sulfate or phase separation filter paper may be used.

10.2.16 Dry the extract in the round bottom flask by filtering it through the sodium sulfate filled funnel. Note that it is not necessary or advisable to

attempt to add the solvent remaining in the continuous extractor body to the extract.

10.2.17 Collect the dried extract in a K-D or other glass container. Rinse the flask that contained the solvent extract with 20-30 mL (5-10 mL for LVI) of methylene chloride and add it to the funnel to complete the quantitative transfer. Dispose of solvent and water remaining in the extractor in the appropriate waste container.

Note: Some types of CLLE apparatus have built in drying columns. If this type of apparatus is used then a drying step subsequent to the extraction may not be necessary.

10.2.18 Cover with aluminum foil if the extract is not concentrated immediately. Refer to Section 10.3 for concentration.

10.3 Concentration

According to the method, type of sample and any cleanup procedures needed, different final solvents and volumes will be required. Refer to Table 2 for the appropriate final volumes and concentrations.

Refer to Figure 3 – Concentration and Cleanup flowchart.

10.3.1 Kuderna-Danish (KD) Method:

10.3.1.1 Assemble a Kuderna-Danish concentrator by attaching a 10 mL concentrator tube to the 500 mL KD flask. For procedures where the final volume is 10 mL or less, a 250 mL Erlenmyer flask may be used as an alternative to the KD flask.

10.3.1.2 Add one or two clean boiling chips and the dried extract to be concentrated to the KD flask and attach a three ball Snyder Column. Add approximately 1 mL of clean methylene chloride to the top of the Snyder column (this is important to ensure that the balls are not stuck and that the column will work properly).

10.3.1.3 Place the KD apparatus on a water bath maintained at 60-65 °C so that the tip of the concentrator tube is submerged. The water level should not reach the joint between the concentrator and the KD flask. At the proper rate of distillation, the balls will actively chatter but the chambers should not flood.

10.3.1.4 Concentrate to 5-15 mL. If the determinative method requires a solvent exchange add the appropriate exchange solvent (see Table 2) to the top of the Snyder Column, and then continue the water bath concentration back down to 1-4 mL. The Snyder column may be insulated if necessary to maintain the correct rate of distillation.

Note: Add an additional boiling chip with the addition of exchange solvent. An alternative technique for solvent exchange is to replace the macro

Snyder column and KD flask with a micro Snyder column, concentrate to approximately 1 mL, add 10 mL of exchange solvent, and concentrate back down to 1 mL. The extract must be cool before the macro Snyder assembly is removed.

Note: It is very important not to concentrate to dryness as analytes will be lost. If this happens, the extract must be discarded and the extraction started over with fresh sample.

10.3.1.5 Remove the KD apparatus from the water bath and allow it to cool for a minimum of 10 minutes. If the level of the extract is above the level of the concentrator tube joint, continue to distill the solvent as necessary. Again, allow the KD flask to cool for a minimum of 10 minutes.

10.3.1.6 If the final volume is 5 or 10 mL, the extract may be made up to volume in the graduated KD tube or transferred to a 12 mL vial previously marked at the appropriate volume level. Document the final volume. Otherwise proceed to section 10.3.2.

10.3.2 Nitrogen Evaporation to Final Concentration

10.3.2.1 Transfer the entire extract to a calibrated evaporation tube. Rinse the concentrator tube with 1-2 mL of the appropriate solvent and transfer the solvent rinsate to the evaporation tube.

10.3.2.2 Place the tube in a warm water bath that is at approximately 35°C and evaporate the solvent using a gentle stream of nitrogen. The nitrogen flow will form a slight depression on the surface of the solvent, but should not create splattering of the extract.

Note: Extracts for method 608.3 may be concentrated at temperature 50-55°C.

10.3.2.3 During the course of the evaporation rinse the sides of the evaporation tube twice with approximately 1 mL of clean solvent. The first rinse should be about half way through the process, with the second rinse when the solvent volume gets close to 1 mL. Concentrate the solvent accurately to the calibrated volume line and transfer the extract to the appropriate storage vial.

Note: It is very important not to concentrate to dryness as analytes will be lost. If this happens, the extract must be discarded and the extraction started over with fresh sample.

Vial Calibration Note: Using a Class A volumetric pipette dispense the appropriate volume of solvent into the vial being calibrated, mark the meniscus and use this vial when marking the final volume line on subsequent sample vials of that type and lot. See SOP PT-QA-026 and work instruction PT-QA-WI-008 for details.

10.3.2.4 An alternative technique is to follow the previous steps concentrating the solvent to slightly below the required final volume and then drawing the extract into a syringe. Rinse the evaporation tube with a small amount of solvent and draw additional solvent into the syringe to make up the accurate final volume.

Note: The final concentration and volume measurement steps are critical. Use care when concentrating and make certain that the final volume measurement is accurate.

10.4 If sample extract cleanup is required please refer to SOP PT-OP-028 for the appropriate cleanup technique.

11.0 CALCULATIONS / DATA REDUCTION

11.1 Not applicable – refer to analytical method SOPs.

12.0 METHOD PERFORMANCE

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2 Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3 Method Detection Limit Study – A Method Detection Limit (MDL) study, as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

13.0 POLLUTION CONTROL

13.1 It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2 Within the constraints of following the methodology in this SOP, use of organic solvents should be minimized.

14.0 WASTE MANAGEMENT

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.1.1 Methylene Chloride extraction waste. This waste is collected in waste containers identified as “Methylene Chloride Waste”, Waste #2.

14.1.2 Extracted water samples. This waste is collected in a waste container identified as “Extraction Water”, Waste #35. The bottom organic layer is drained into a container identified as “Methylene Chloride Waste”, Waste #2. The remaining aqueous layer is neutralized to a pH between 6 and 9 and discharged down lab sink/ drain.

14.1.3 Used sodium sulfate and glass wool or filter paper contaminated with methylene chloride from the extract drying step. This waste is collected in a container identified as “Lab Trash Waste”, Waste #12.

14.1.4 Assorted flammable solvent waste from various rinses. This waste is collected in waste containers identified as “Mixed Flammable Solvent Waste”, Waste 3.

14.1.5 Methylene chloride waste from various rinses. This waste is collected in waste containers identified as “Methylene Chloride Waste”, Waste #2.

14.1.6 Miscellaneous disposable glassware contaminated with acids, caustics, solvents and sample residue. This waste is collected in a container identified as “Lab Trash Waste”, Waste #12.

16.0 METHOD MODIFICATIONS

16.1 Some surrogate spiking concentrations are modified from those recommended in SW-846, in order to make the concentrations more consistent with the calibration levels in the determinative methods.

16.2 Spiking levels for method 608.3 have been reduced by a factor of ten to bring the levels within the normal calibration range of the instrument.

SECTION 3
INTRODUCTION, SCOPE AND APPLICABILITY

3.1 INTRODUCTION AND COMPLIANCE REFERENCES

Eurofins TestAmerica Pittsburgh's Quality Assurance Manual (QAM) is a document prepared to define the overall policies, organization objectives and functional responsibilities for achieving Eurofins TestAmerica's data quality goals. The laboratory maintains a local perspective in its scope of services and client relations and maintains a national perspective in terms of quality.

The QAM has been prepared to assure compliance with The NELAC Institute (TNI) Standard, dated 2009, Volume 1 Modules 2 and 4, and ISO/IEC Guide 17025:2017(E). In addition, the policies and procedures outlined in this manual are compliant with Eurofins TestAmerica's Corporate Quality Management Plan (CQMP) CA-Q-M-002, and the various accreditation and certification programs listed in Appendix 3. The CQMP provides a summary of Eurofins TestAmerica's quality and data integrity system. It contains requirements and general guidelines under which all Eurofins TestAmerica facilities shall conduct their operations.

This QAM has been prepared to be consistent with requirements of the following documents:

- EPA *Requirements for Quality Management Programs* (QA/R-2), EPA/240/B-01/002, May 31, 2006
- EPA 600/4-88/039, *Methods for the Determination of Organic Compounds in Drinking Water,* EPA, Revised July 1991
- EPA 600/R-95/131, *Methods for the Determination of Organic Compounds in Drinking Water,* Supplement III, EPA, August 1995
- EPA 600/4-79-019, *Handbook for Analytical Quality Control in Water and Wastewater Laboratories,* EPA, March 1979
- *Test Methods for Evaluating Solid Waste Physical/Chemical Methods (SW846), Third Edition, September 1986, Final Update I, July 1992, Final Update IIA, August 1993, Final Update II, September 1994; Final Update IIB, January 1995; Final Update III, December 1996; Final Update IV, January 2008, Final Update V, August 2015*

- Toxic Substances Control Act (TSCA)

3.2 TERMS AND DEFINITIONS

A Quality Assurance Program is a company-wide system designed to ensure that data produced by the laboratory conforms to the standards set by state and/or federal regulations. The program functions at the management level through company goals and management policies, and at the analytical level through Standard Operating Procedures (SOPs) and quality control. The Eurofins TestAmerica program is designed to minimize systematic error, encourage constructive, documented problem solving, and provide a framework for continuous improvement within the organization.

Refer to Appendix 2 for the Glossary/Acronyms.

3.3 SCOPE / FIELDS OF TESTING

The laboratory analyzes a broad range of environmental and industrial samples. Sample matrices vary among effluent water, surface water, groundwater, hazardous waste, sludge, soils, sediments, and tissue. The Quality Assurance Program contains specific procedures and methods to test samples of differing matrices for chemical, physical and biological parameters. The Program also contains guidelines on maintaining documentation of analytical processes, reviewing results, servicing clients and tracking samples through the laboratory. The technical and service requirements of all analytical requests are thoroughly evaluated before commitments are made to accept the work. Measurements are made using published reference methods or methods developed and validated by the laboratory.

The methods covered by this manual include the most frequently requested methodologies needed to provide analytical services in the United States and its territories. The specific list of test methods used by the laboratory can be found in the Statement of Qualifications (SOQ). The current list of accredited methods is maintained in Total Access. The approach of this manual is to define the minimum level of quality assurance and quality control necessary to meet these requirements. All methods performed by the laboratory shall meet these criteria as appropriate. In some instances, quality assurance project plans (QAPPs), project specific data quality objectives (DQOs) or local regulations may require criteria other than those contained in this manual. In these cases, the laboratory will abide by the requested criteria following review and acceptance of the requirements by the Laboratory Director and the Quality Assurance (QA) Manager. In some cases, QAPPs and DQOs may specify less stringent requirements. The Laboratory Director and the QA Manager must determine if it is in the lab's best interest to follow the less stringent requirements.

3.3.1 Specialty Analyses

3.3.1.1 Dredged Material Evaluations

Eurofins TestAmerica Pittsburgh offers trace level testing of waters (site-waters and elutriates), sediments, and tissues in support of Dredged Material Evaluations for in-water (ocean and inland waters) and upland (Confined Disposal Facilities (CDFs), beneficial use, etc.) disposal options. In-house capabilities for commonly requested sediment program parameters include:

- Organochlorine Pesticides
- Organophosphorus Pesticides
- PCBs (as Aroclors and Congeners)
- Volatile Organics
- Semivolatile Organics
- Metals
- Cyanide
- Total Sulfides
- Acid Volatile Sulfide (AVS) and Simultaneously Extracted Metals (SEM)
- Nitrogen, Ammonia
- Nitrogen, Nitrate + Nitrite
- Biochemical Oxygen Demand (BOD)
- Chemical Oxygen Demand (COD)
- Total Organic Carbon (combustion procedure for sediments)

- Total Solids/Moisture Content
- Total Volatile Solids
- Lipids
- With teaming arrangements with other Eurofins TestAmerica facilities, additional sediment program capabilities include:
    - Polychlorinated Dibenzo-Dioxins and Furans (PCDDs/PCDFs)
    - Butyl Tins (mono – tetra)
    - Total Kjeldahl Nitrogen
    - Total Phosphorus
    - Grain Size
    - Specific Gravity
    - Atterberg Limits

Eurofins TestAmerica Pittsburgh also generates elutriate samples following appropriate U.S. Army Corps of Engineers procedures. These include:

- Standard Elutriate Test (SET) for in-water disposal evaluations, and
- Modified Elutriate Test (MET) or Effluent Elutriate Test (EET) for CDF disposal evaluations.
- Illinois Resuspension Tests (Supernatant and Elutriate Tests).
- Dredge Elutriate Test (DRET)

Eurofins TestAmerica Pittsburgh currently supports dredge material evaluation projects following several state specific programs, as well as, under the following guidance documents:

- Ocean Testing Manual or OTM (USACE, 1991).
- New Jersey's Tidal Waters Technical Manual (NJDEP, 1997).
- Inland Testing Manual or ITM (USACE, 1998).
- Upland Testing Manual or UTM (USACE, 2003).

3.3.1.2 Tissue Analyses

Eurofins TestAmerica Pittsburgh has extensive experience in supporting projects requiring tissue analyses. These include analyses of laboratory cultured reference species from bioaccumulation tests associated with dredged material evaluations to a variety of field collected species (aquatic and terrestrial). Eurofins TestAmerica Pittsburgh has developed modifications to the standard solid methodologies (where possible) to allow for the use of smaller sample weights and achieve lower quantitation limits. In-house capabilities for commonly requested tissue parameters include:

- Organochlorine Pesticides
- PCBs (as Aroclors and Congeners)
- Semivolatile Organics
- Metals
- Lipids
- Moisture Content

- With teaming arrangements with other Eurofins TestAmerica facilities, additional tissue capabilities include:
  - Polychlorinated Dibenzo-Dioxins and Furans (PCDDs/PCDFs)
  - Butyl Tins (mono – tetra)

3.4 MANAGEMENT OF THE MANUAL

3.4.1 Review Process

The template on which this manual is based is reviewed annually by Corporate Quality Management Personnel to assure that it remains in compliance with Section 3.1. This manual itself is reviewed every two years by senior laboratory management to assure that it reflects current practices and meets the requirements of the laboratory's clients and regulators as well as the CQMP. Occasionally, the manual may need changes in order to meet new or changing regulations and operations. The QA Manager will review the changes in the normal course of business and incorporate changes into revised sections of the document. All updates will be reviewed by the senior laboratory management staff. The laboratory updates and approves such changes according to Pittsburgh laboratory SOP No. PT-QA-010, *Document Development and Control*.

SECTION 4

MANAGEMENT REQUIREMENTS

4.1 Overview

Eurofins TestAmerica Pittsburgh is a local operating unit of Eurofins TestAmerica Laboratories, Inc.. The organizational structure, responsibilities and authorities of the Corporate staff of TestAmerica Laboratories, Inc. are presented in the CQMP. The laboratory has day-to-day independent operational authority overseen by corporate officers (e.g., President and Chief Executive Officer (CEO), Chief Operating Officer (COO), Executive Vice President (VP) Operations, Corporate Quality etc.). The laboratory operational and support staff work under the direction of the Laboratory Director. The organizational structure for both Corporate & Eurofins TestAmerica Pittsburgh is presented in Figure 4-1.

4.2 Roles And Responsibilities

In order for the Quality Assurance Program to function properly, all members of the staff must clearly understand and meet their individual responsibilities as they relate to the quality program. The following descriptions briefly define each role in its relationship to the Quality Assurance Program.

4.2.1 Additional Requirements for Laboratories

The responsibility for quality resides with every employee of the laboratory. All employees have access to the QAM, are trained to this manual, and are responsible for upholding the standards therein. Each person carries out his/her daily tasks impartially and in a manner consistent with the goals and in accordance with the procedures in this manual and the laboratory's SOPs. Role descriptions for corporate personnel are defined in the CQMP. This manual is specific to the operations of Eurofins TestAmerica's Pittsburgh laboratory.

4.2.2 President and Chief Executive Officer (CEO)

The President and CEO is a member of the Board of Directors and is ultimately responsible for the quality and performance of all Eurofins TestAmerica facilities. The President and CEO establishes the overall quality standard and data integrity program for the Analytical Business, providing the necessary leadership and resources to assure that the quality standard and integrity program are met.

4.2.3 Chief Operation Officer (COO)

The COO reports directly to the President and CEO of Eurofins TestAmerica. The COO is responsible for the operations of Eurofins TestAmerica's subsidiary companies and the company's strategic growth.

4.2.4 Senior Vice President of Operations and Client Services

The SVP of Operations and Client Services leads the Client Services Organization (CSO) and oversees the operations of all Eurofins TestAmerica Laboratories, the Corporate Technical Services group and the Sales Opportunity Optimization efforts. The SVP provides direction to the VPs of Operations, Client Services Directors, Manager or Project Managers, Director of Technical Services and a Director of Sales. The SVP of Operations and Client Services reports directly to the President and CEO of Eurofins TestAmerica.

4.2.5 Vice President of Operations (VPO)

Each VP of Operations (VPO) reports directly to the SVP of Operations and Client Services. Each VPO is responsible for the overall administrative and operational management of their respective laboratories. The VPO's responsibilities include allocation of personnel and resources, long-term planning, goal setting, and achieving the financial, business, and quality objectives of Eurofins TestAmerica. The VPOs ensure timely compliance with Corporate Management directives, policies, and management systems reviews. The VPOs are also responsible for restricting any laboratory from performing analyses that cannot be consistently and successfully performed to meet the standards set forth in this manual.

4.2.6 Vice President of Quality and Environmental Health and Safety (VP-QA/EHS)

The Vice President (VP) of QA/EHS reports directly to the President and CEO. With the aid of the Executive Committee, Laboratory Directors, Quality Directors, Safety Managers, EH&S Coordinators and QA Managers, the VP-QA/EHS has the responsibility for the establishment, general overview and Corporate maintenance of the Quality Assurance and EH&S Programs within Eurofins TestAmerica. Additional responsibilities include:

- Review of QA/QC and EHS aspects of Corporate SOPs & Policies, national projects and expansions or changes in services.
- Work with various organizations outside of Eurofins TestAmerica to further the development of quality standards and represent Eurofins TestAmerica at various trade meetings.
- Prepare monthly reports for quality and EH&S metrics across the analytical laboratories and a summary of any quality related initiatives and issues.
- With the assistance of the Corporate Senior Management Teams and the EHS Managers, development and implementation of the Eurofins TestAmerica Environmental, Health and Safety Program.

4.2.7 Quality Assessment Director

The Quality Assessment Director reports to the VP-QA/EHS. The Quality Assessment Director has QA oversight of laboratories; is responsible for the internal audit system, schedule and procedure; monitors laboratory internal audit findings; identifies common laboratory weaknesses; and monitors corrective action closures. Together with the Quality Compliance Director, the Quality Systems Director, and the VP-QA/EHS, the Quality Assessment Director has the responsibility for the establishment, general overview and maintenance of the Analytical Quality Assurance Program within Eurofins TestAmerica.

4.2.8 Quality Compliance Director

The Quality Compliance Director reports to the VP-QA/EHS. The Quality Compliance Director has QA oversight of laboratories; monitors and communicates DoD / DoE requirements; develops Corporate tools for ensuring and improving compliance; develops Corporate assessment tools; identifies common laboratory weaknesses; and monitors corrective action closures. Together with the Quality Assessment Director, Quality Systems Director and the VP-QA/EHS, the Quality Compliance Director has the responsibility for the establishment, general overview and maintenance of the Analytical Quality Assurance Program within Eurofins TestAmerica.

4.2.9 Quality Systems Director

The Quality Systems Director reports to the VP-QA/EHS. The Quality Systems Director has QA oversight of laboratories; develops quality policies, procedures and management tools; monitors and communicates regulatory and certification requirements; identifies common laboratory weaknesses; and monitors corrective action closures. Together with the Quality Assessment Director, Quality Compliance Director and the VP-QA/EHS, the Quality Systems Director has the responsibility for the establishment, general overview and maintenance of the Analytical Quality Assurance Program within Eurofins TestAmerica.

4.2.10 Quality Information Manager

The Quality Information Manager is responsible for managing all company official documents (e.g., Policies, Procedures, Work Instructions), the company's accreditation database, intranet websites, external laboratory subcontracting, regulatory limits for clients on the company's TotalAccess website; internal and external client support for various company groups (e.g., Client Services, EH&S, Legal, IT, Sales) for both quality and operational functions. The Quality Information Manager reports to the VP-QA/EHS; and works alongside the Quality Assessment, Quality Compliance and Quality System Directors and EHS Managers to support both the Analytical Quality Assurance and EHS Programs within Eurofins TestAmerica.

4.2.11 Technical Services Director

The Technical Services Director is responsible for establishing, implementing and communicating Eurofins TestAmerica's Analytical Business's Technical Policies, SOPs, and Manuals. Other responsibilities include conducting technical assessments as required, acting as a technical resource in national contracts review, coordinating new technologies, establishing best practices, advising staff on technology advances, innovations, and applications.

4.2.12 Ethics and Compliance Officers (ECOs)

Eurofins TestAmerica has designated two senior members of the Corporate staff to fulfill the role of Ethics and Compliance Officer (ECO) – i.e., the Corporate Counsel & VP of Human Resources and the VP-QA/EHS. Each ECO acts as a back-up to the other ECO and both are involved when data investigations occur. Each ECO has a direct line of communication to the entire senior Corporate and lab management staff.

The ECOs ensure that the organization distributes the data integrity and ethical practices policies to all employees and ensures annual trainings and orientation of new hires to the ethics program and its policies. The ECO is responsible for establishing a mechanism to foster employee reporting of incidents of illegal, unethical, or improper practices in a safe and confidential environment.

The ECOs monitor and audit procedures to determine compliance with policies and to make recommendations for policy enhancements to the President and CEO, VPOs, Laboratory Director or other appropriate individuals within the laboratory. The ECO will assist the laboratory QA Manager in the coordination of internal auditing of ethical policy related activities and processes within the laboratory, in conjunction with the laboratory's regular internal auditing function.

The ECOs will also participate in investigations of alleged violations of policies and work with the appropriate internal departments to investigate misconduct, remedy the situation, and prevent recurrence of any such activity.

4.2.13 Chief Information Officer (CIO)

The CIO is responsible for establishing, implementing and communicating Eurofins TestAmerica's Information Technology (IT) Policies, SOPs and Manuals. Other responsibilities include coordinating new technologies, development of electronic communication tools such as Eurofins TestAmerica's intranet and internet sites, ensuring data security and documentation of software, ensuring compliance with the NELAC standard, and assistance in establishing, updating, and maintaining Laboratory Information Management Systems (LIMS) at the various Eurofins TestAmerica facilities.

4.2.14 Environmental Health and Safety Managers (Corporate)

The EHS Managers report directly to the VP-QA/EHS. The EHS Managers are responsible for the development and implementation of the Eurofins TestAmerica Environmental, Health and Safety program. Responsibilities include:

- Consolidation and tracking all safety and health-related information and reports for the company, and managing compliance activities for Eurofins TestAmerica locations
- Coordination/preparation of the Corporate Environmental, Health and Safety Manual Template that is used by each laboratory to prepare its own laboratory-specific Safety Manual/ CHP
- Preparation of information and training materials for laboratory EHS Coordinators
- Assistance in the coordination of employee exposure and medical monitoring programs to insure compliance with applicable safety and health regulations

- Serving as Department of Transportation (D.O.T.) focal point and providing technical assistance to location management
- Serving as Hazardous Waste Management main contact and providing technical assistance to location management

4.2.15 Laboratory Director (Business Unit Manager or BUMA)

Pittsburgh's Laboratory Director is responsible for the overall quality, safety, financial, technical, human resource and service performance of the whole laboratory and reports to their respective GM. The Laboratory Director is also responsible for any service centers connected with their laboratory that perform any tests, such as short holding time analysis for pH. The Laboratory Director provides the resources necessary to implement and maintain an effective and comprehensive Quality Assurance and Data Integrity Program. The Laboratory Director can also serve as the Technical Manager.

Specific responsibilities include, but are not limited to:

- Providing one or more technical managers for the appropriate fields of testing. If the Technical Manager is absent for a period of time exceeding 15 consecutive calendar days, the Laboratory Director must designate another full time staff member meeting the qualifications of the Technical Manager to temporarily perform this function. If the absence exceeds 20 consecutive calendar days, the primary accrediting authority must be notified in writing.
- Ensuring that all analysts and supervisors have the appropriate education and training to properly carry out the duties assigned to them and ensures that this training has been documented.
- Ensuring that personnel are free from any commercial, financial and other undue pressures which might adversely affect the quality of their work.
- Ensuring Eurofins TestAmerica's human resource policies are adhered to and maintained.
- Ensuring that sufficient numbers of qualified personnel are employed to supervise and perform the work of the laboratory.
- Ensuring that appropriate corrective actions are taken to address analyses identified as requiring such actions by internal and external performance or procedural audits. Procedures that do not meet the standards set forth in the QAM or laboratory SOPs may be temporarily suspended by the Laboratory Director.
- Reviewing and approving all SOPs prior to their implementation and ensures all approved SOPs are implemented and adhered to.
- Pursuing and maintaining appropriate laboratory certification and contract approvals. Supports ISO 17025 requirements.
- Ensuring client specific reporting and quality control requirements are met.
- Captaining the management team, consisting of the QA Manager, the Technical Managers and the Department Managers.
- Monitoring the validity of the analyses performed and data generated in the laboratory.
- Providing training and development programs to applicable laboratory staff as new hires and, on a scheduled basis. Training includes instruction on calculations, instrumentation management to include troubleshooting and preventive maintenance.
- The Technical Manager meets the requirements specified in the Section 5.2.6.1 of the TNI standards.

4.2.16 Quality Assurance (QA) Manager or Designee

The QA Manager has responsibility and authority to ensure the continuous implementation of the quality system at the laboratory where they work. The QA Manager is also responsible for any service centers connected with their laboratory that perform any tests, such as short holding time analysis for pH. The QA Manager reports directly to the Laboratory Director and their Corporate Quality Director. This position is able to evaluate data objectively and perform assessments without outside (e.g., managerial) influence. Corporate QA may be used as a resource in dealing with regulatory requirements, certifications and other quality assurance related items. The QA Manager directs the activities of the QA Specialists to accomplish specific responsibilities, which include, but are not limited to:

- Serving as the focal point for QA/QC in the laboratory.
- Having functions independent from laboratory operations for which he/she has quality assurance oversight.
- Maintaining and updating the QAM.
- Monitoring and evaluating laboratory certifications; scheduling proficiency testing samples.
- Monitoring and communicating regulatory changes that may affect the laboratory to management.
- Training and advising the laboratory staff on quality assurance/quality control procedures that are pertinent to their daily activities.
- Having documented training and/or experience in QA/QC procedures and the laboratory's Quality System.
- Having a general knowledge of the analytical test methods for which data audit/review is performed (and/or having the means of getting this information when needed).
- Arranging for or conducting internal audits on quality systems and the technical operation.
- Maintaining records of all ethics-related training, including the type and proof of attendance.
- Maintaining, improving, and evaluating the corrective action database and the corrective and preventive action systems.
- Notifying laboratory management of deficiencies in the quality system and ensuring corrective action is taken. Procedures that do not meet the standards set forth in the QAM or laboratory SOPs shall be investigated following procedures outlined in Section 12 and if deemed necessary may be temporarily suspended during the investigation.
- Objectively monitoring standards of performance in quality control and quality assurance without outside (e.g., managerial) influence.
- Having the responsibility and final authority to accept or reject data and to stop work in progress in the event that procedures and practices compromise the validity and integrity of analytical data.
- Coordinating of document control of SOPs, MDLs, control limits, and miscellaneous forms and information. Controlling distribution of controlled documents.
- Reviewing a percentage of all final data reports for internal consistency, including Chain of Custody (COC), correspondence with the analytical request, batch QC status, completeness

of any corrective action statements, 5% of calculations, format, holding time, sensibility and completeness of the project file contents.

- Reviewing of external audit reports and data validation requests.
- Following-up with audits to ensure client QAPP requirements are met.
- Establishing reporting schedule and preparation of various quality reports for the Laboratory Director, clients and/or Corporate QA.
- Developing suggestions and recommendations to improve quality systems.
- Researching current state and federal requirements and guidelines.
- Captaining the QA team to enable communication and to distribute duties and responsibilities.
- Ensuring Communication & monitoring standards of performance to ensure that systems are in place to produce the level of quality as defined in this document.
- Evaluating the thoroughness and effectiveness of training.
- Ensuring Compliance with ISO 17025, and other national and state programs, as applicable
- Notifying the accrediting authorities within 30 days of a change in the legal name of the laboratory or a change in any information provided on the application submitted for accreditation.
- Notifying the primary accrediting authority of any change in the laboratories ability to produce valid analytical results that persists for more than 90 calendar days for any analyte/method/matrix combination for which the laboratory holds accreditation.

4.2.17 Technical Director

The Technical Director reports directly to the Laboratory Director. He/she is accountable for all analyses and analysts under their experienced supervision and for compliance with the ISO 17025:2017 standard. He/she serves as a technical resource for Eurofins TestAmerica's personnel and clients in their field of expertise. The scope of responsibility ranges from the new-hire process and existing technology through on-going training and development programs for existing analysts and new instrumentation, Specific responsibilities include, but are not limited to:

- Managing technical projects and evaluating technologies, reviewing technical data
- Solving technical problems in the laboratory including troubleshooting instruments and developing or modifying methods as needed to meet customer requirements.
- Maintaining and repairing analytical instruments to reduce downtime.
- Consulting with clients, regulators, and others regarding technical aspects of analyses.
- Suggesting and implementing process improvements to maximize productivity, save costs, and decrease turn-around time.
- Participating in Eurofins TestAmerica's best practice process to spread best technical practices and developing Eurofins TestAmerica Standard Operating Procedures (SOPs). Leads the implementation and follow-up of the best practices and SOPs in the laboratory.
- Evaluating and adapting new technologies and methodologies. Performs non-routine analysis as required to meet the needs of current long-term clients or as a means to capture new clients in support of business development efforts.
- Training analysts and technicians in area of expertise.
- Assisting with the development of health and safety protocols.

- Consulting with Project Managers and sales staff regarding analytical techniques and capabilities.
- Investigating issues raised by clients, QA, sales, and other departments to find root cause and implement corrective action and proper response.
- Contributing technical information and evaluation for deciding major new equipment purchases and capital expenditures.
- Ensuring compliance with ISO 17025, and other national and state programs.

4.2.18 Quality Assurance Specialist

The QA Specialist is responsible for QA documentation and involvement in the following activities:

- Assisting the QA Manager in performing the annual internal laboratory audits, compiling the evaluation, and coordinating the development of an action plan to address any deficiency identified.
- Facilitating external audits, coordinating with the QA Manager and Laboratory Staff to address any deficiencies noted at the time of the audit and subsequently presented in the final audit report.
- Assisting the QA Manager in the preparation of new SOPs and in the maintenance of existing SOPs, coordinating annual reviews and updates.
- Managing the performance testing (PT) studies, coordinates follow up studies for failed analytes and works with QA Manager and Laboratory Staff to complete needed corrective action reports.
- Assisting with review and maintenance of training records.
- Assisting the Quality Manager and Project Management Group in the review of program plans for consistency with organizational and contractual requirements. Summarize and convey to appropriate personnel anomalies or inconsistencies observed in the review process.
- Assisting with management of and applications for certifications and accreditations.
- Monitoring for compliance the following QA Metrics: temperature monitoring of refrigeration units and incubators; thermometer calibrations; balance calibrations; Eppendorf/pipette calibrations; and proper standard/reagent storage.
- Performing Technical Data Audits and the Audit Miner data file review process for organic instrumentation. Maintain tracking of reviews.
- Assisting with technical review of data packages which require QA review.

4.2.19 Technical Manager / Department Manager

The Technical Manager reports directly to the Laboratory Director. The scope of responsibility ranges from the new-hire training and existing technology through the ongoing training and development programs for existing analysts and new instrumentation and for compliance with the ISO 17025 Standard. Specific responsibilities include, but are not limited to:

- Exercising day-to-day supervision of laboratory operations for the appropriate field of accreditation and reporting of results. Coordinating, writing, and reviewing preparation of all test methods, i. e., SOPs, with regard to quality, integrity, regulatory and optimum and efficient production techniques, and subsequent analyst training and interpretation of the SOPs for implementation and unusual project samples. He/she insures that the SOPs are properly managed and adhered to at the bench. He/she develops standard costing of SOPs

to include supplies, labor, overhead, and capacity (design vs. demonstrated versus first-run yield) utilization.

- Reviewing and approving, with input from the QA Manager, proposals from marketing, in accordance with an established procedure for the review of requests and contracts. This procedure addresses the adequate definition of methods to be used for analysis and any limitations, the laboratory's capability and resources, the client's expectations. Differences are resolved before the contract is signed and work begins. A system documenting any significant changes is maintained, as well as pertinent discussions with the client regarding their requirements or the results of the analyses during the performance of the contract. All work subcontracted by the laboratory must be approved by the client. Any deviations from the contract must be disclosed to the client. Once the work has begun, any amendments to the contract must be discussed with the client and so documented.
- Monitoring the validity of the analyses performed and data generated in the laboratory. This activity begins with reviewing and supporting all new business contracts, insuring data quality, analyzing internal and external non-conformances to identify root cause issues and implementing the resulting corrective and preventive actions, facilitating the data review process (training, development, and accountability at the bench), and providing technical and troubleshooting expertise on routine and unusual or complex problems.
- Providing training and development programs to applicable laboratory staff as new hires and, subsequently, on a scheduled basis. Training includes instruction on calculations, instrumentation management to include troubleshooting and preventive maintenance.
- Enhancing efficiency and improving quality through technical advances and improved LIMS utilization. Capital forecasting and instrument life cycle planning for second generation methods and instruments as well as asset inventory management.
- Coordinating sample management from "cradle to grave," insuring that no time is lost in locating samples.
- Scheduling all QA/QC-related requirements for compliance, e.g., MDLs, etc..
- Captaining department personnel to communicate quality, technical, personnel, and instrumental issues for a consistent team approach.
- Coordinating audit responses with the QA Manager.
- Ensuring compliance with ISO 17025, and other national and state programs

4.2.20 Manger of Project Management

The Manager of Project Management reports directly to the Client Services Director with dotted line reporting to the Laboratory Director. There is an entire staff of Project Managers that makes up the Project Management team. With the overall goal of total client satisfaction. In addition to the responsibilities of the Project Manager, listed in section 4.2.21, the MPM's responsibilities include, but are not limited to:

- Training project managers in technical procedures and promoting the growth of the Project Management Team
- Acting as liaison between laboratory management and the Project Management Team
- Managing human resources for the Project Management Team

4.2.21 Project Manager

The PM reports to the Manager of Project Management and serves as the interface between the laboratory's technical departments and the laboratory's clients. The responsibilities of this position include, but are not limited to:

- Ensuring that clients receive the proper sampling supplies
- Responding to client inquiries concerning sample status
- Assisting clients with the resolution of problems concerning COC
- Ensuring that client specifications, when known, are met by communicating project and quality assurance requirements to the laboratory
- Notifying the supervisors of incoming projects and sample delivery schedules
- Maintaining communication with clients on sample progress from daily status meeting with agreed-upon due dates
- Discussing with client any project-related problems, resolving service issues, and coordinating technical details with the laboratory staff
- Familiarizing laboratory staff with specific quotes, sample log-in review, and final report completeness
- Informing QA Manager of special client requests that are outside of standard operating procedure
- Monitoring the status of all data package projects in-house to ensure timely and accurate delivery of reports
- Informing clients of data package-related problems and resolve service issues
- Coordinating requests for sample containers and other services
- Verifying that subcontract laboratories hold the required certification for all analytes, methods, and matrices to be sent.

4.2.22 Project Manager Assistant (PMA)

The PMA reports to the Manager of Project Management and serves as the interface between the laboratory's technical departments and the laboratory's clients. The responsibilities of this position include, but are not limited to:

- Collating data reports, expanded deliverables and CLP data packages for delivery to clients and reviews for accuracy
- Assisting the CSMs and PMs in the reporting process
- Printing reports as needed for Project Managers
- Monitoring report due dates for timely delivery
- Providing clerical support to the CSMs, PMs and other laboratory staff as needed
- Generating credit or debit invoices to ensure proper payment in compliance with client requirements as established and communicated
- Sending final data to clients via email or courier

4.2.23 Team Leader/Supervisor

The Team Leader/Supervisor reports directly to the Organics or Inorganics Manager and/or Laboratory Director or designee. The responsibilities of this position include, but are not limited to:

- Ensuring that analysts in their department adhere to applicable SOPs and the QA Manual. He/she performs frequent SOP review to determine if analysts are in compliance and if new, modified, and optimized measures are feasible and should be added to these documents.
- Overseeing training, development of performance objectives and standards of performance, appraisal (measurement of objectives), scheduling, counseling, discipline, and motivation of analysts and documents these activities in accordance with systems developed by the QA and Personnel Departments.
- Providing guidance to analysts in resolving problems encountered daily during sample prep/analysis in conjunction with the Technical Manager(s) and/or QA Manager. Each is responsible ensuring 100% implementation of the data review and documentation, non-conformance and corrective action issues, the timely and accurate completion of performance evaluation samples and MDLs, for his/her department.
- Ensuring that all logbooks are maintained, current, and properly labeled or archived.
- Ensuring that all data is properly entered into the LIMS system and is reviewed and approved as required by laboratory documentation policy.
- Reporting all non-conformance conditions to the QA Manager and Department Manager.
- Ensuring that preventive maintenance is performed on instrumentation as detailed in the QA Manual or SOPs. He/she is responsible for developing and implementing a system for preventive maintenance, troubleshooting, and repairing or arranging for repair of instruments.
- Maintaining adequate and valid inventory of reagents, standards, spare parts, and other relevant resources required to perform daily analysis.
- Achieving optimum turnaround time on analyses and compliance with holding times.
- Assisting QA department with root cause investigations and corrective action proposals for responses to external and internal audit issues, system failures and client complaints.

4.2.24 Laboratory Analyst

Laboratory analysts are responsible for conducting analysis and performing all tasks assigned to them by the team leader or supervisor. The responsibilities of the analysts include, but are not limited to:

- Performing analyses by adhering to analytical and quality control protocols prescribed by current SOPs, this QA Manual, and project-specific plans honestly, accurately, timely, safely, and in the most cost-effective manner.
- Ensuring sample and data integrity by adhering to internal chain-of-custody procedures.
- Documenting standard and sample preparation, instrument calibration and maintenance, data calculations, sample matrix effects, and any observed non-conformance on bench sheets, lab notebooks, run logs, and/or the Non-Conformance Database.
- Reporting all non-conformance situations, instrument problems, matrix problems and QC failures, which might affect the reliability of the data, to their supervisor, Department Manager, and/or the QA Manager or member of QA staff.
- Performing 100% review of the data generated prior to entering and submitting for secondary level review. Performs data processing using available tools/software.
- Suggesting method improvements to their supervisor, the Technical Manager (s), and the QA Manager. These improvements, if approved, will be incorporated. Ideas for the

optimum performance of their assigned area, for example, through the proper cleaning and maintenance of the assigned instruments and equipment, are encouraged.

- Working cohesively as a team in their department to achieve the goals of accurate results, optimum turnaround time, cost effectiveness, cleanliness, complete documentation, and personal knowledge of environmental analysis.
    - A "work cell" is considered to be all those individuals who see a sample through the complete process of preparation, extraction, and analysis. To ensure that the entire preparation, extraction, and analysis process is completed by a group of capable individuals, the laboratory shall ensure that each member of the work cell (including a new member entering an already existing work cell) demonstrates capability in his/her area of responsibility in the sequence. Even though the work cell operates as a "team," the demonstration of capability at each individual step in the sequence, as performed by each individual analyst/team member, remains of utmost importance. A work cell may NOT be defined as a group of analysts who perform the same step in the same process (for example, extractions for Method 8270), represented by one analyst who has demonstrated capability for that step.

4.2.25 Sample Management Manager

The Sample Receiving Manager reports to the Laboratory Director and Client Services Manager. The responsibilities of this position include, but are not limited to:

- Ensuring implementation of proper sample receipt procedures, including maintenance of chain-of-custody.
- Reporting nonconformances associated with condition-upon-receipt of samples.
- Ensuring accurate login of samples into TALS.
- Ensuring that all samples are stored in the proper environment.
- Assisting Environmental Health and Safety staff with sample disposal.

4.2.26 Field Service Technician

The Field Service Technicians report to the Sample Management Department Manager. The responsibilities of the Field Service Technician include, but are not limited to:

- Performing sample collection and sample pick-up
- Ensuring sample containers are prepared for sampling
- Performing field tests and measurements and operating and maintaining equipment used for those purposes.

4.2.27 Environmental Health and Safety Coordinator

The Health and Safety Coordinator reports to the Laboratory Director and ensures that systems are maintained for the safe operation of the laboratory. The EH&S Coordinator :

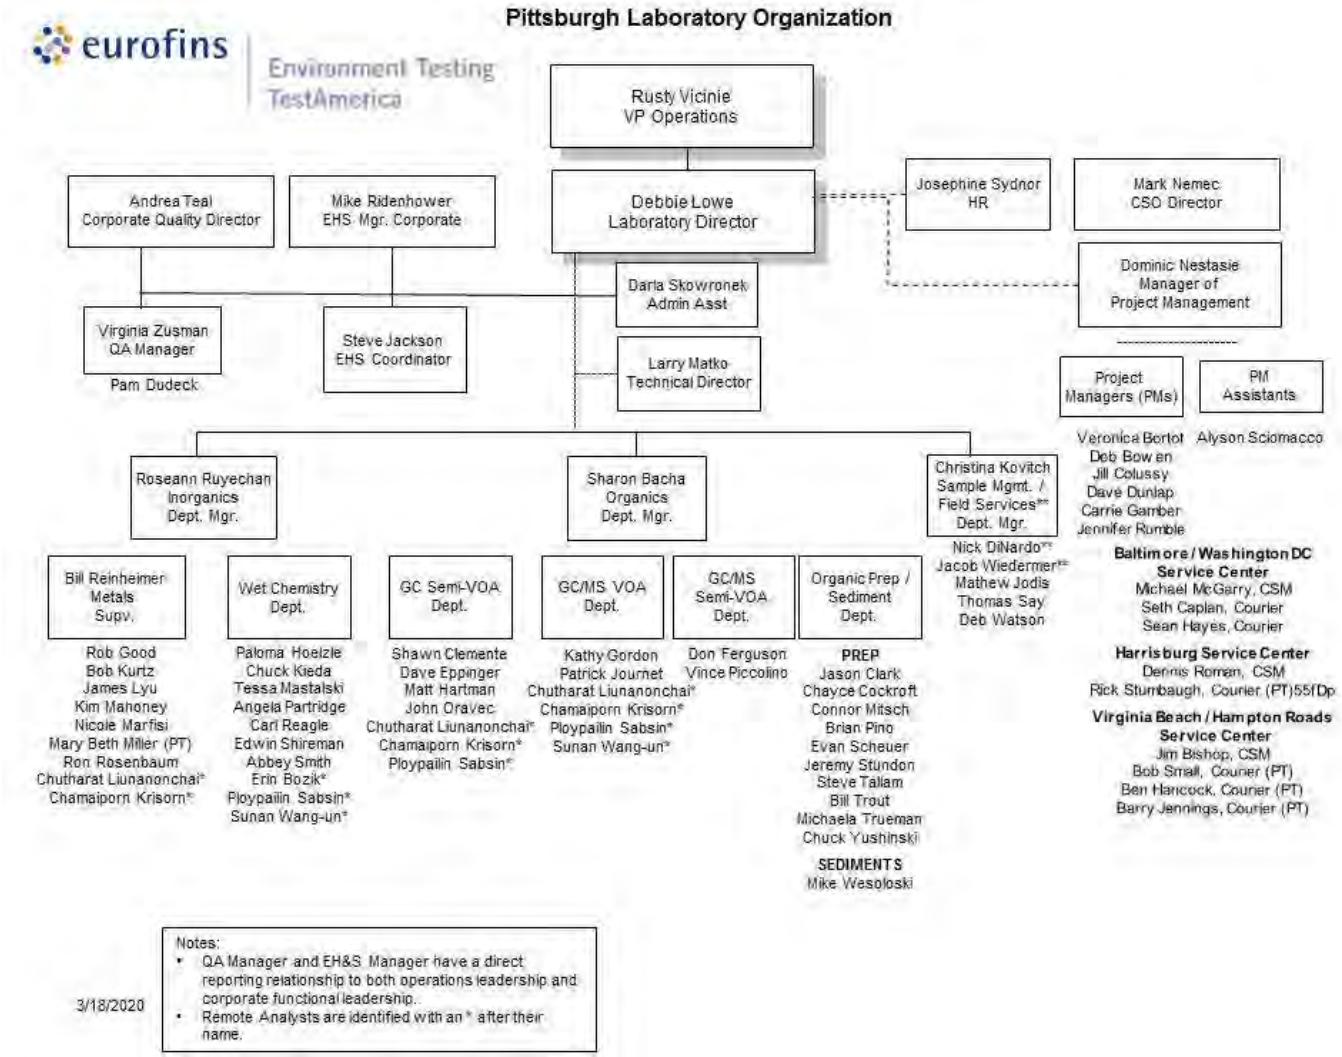
- Conduct ongoing, necessary safety training and conduct new employee safety orientation.
- Assist in developing and maintaining the Chemical Hygiene/Safety Manual.
- Administer dispersal of all Safety Data Sheet (SDS) information.
- Perform regular chemical hygiene and housekeeping instruction.
- Give instruction on proper labeling and practice.
- Serve as chairman of the laboratory safety committee.
- Provide and train personnel on protective equipment.
- Oversee the inspection and maintenance of general safety equipment – fire extinguishers, safety showers, eyewash fountains, etc. and ensure prompt repairs as needed.

- Supervise and schedule fire drills and emergency evacuation drills.
- Determine what initial and subsequent exposure monitoring, if necessary to determine potential employee exposure to chemicals used in the laboratory.
- When determined necessary, conduct exposure monitoring assessments.
- Determine when a complaint of possible over-exposure is "reasonable" and should be referred for medical consultation.
- Assist in the internal and external coordination of the medical consultation/monitoring program conducted by Eurofins TestAmerica's medical consultants.

4.2.28 Hazardous Waste Coordinator

The Hazardous Waste Coordinator reports directly to the Laboratory Director. The duties include, but are not limited to:

- Staying current with the hazardous waste regulations
- Continuing training on hazardous waste issues
- Reviewing and updating annually the Hazardous Waste Contingency Plan in the Environmental Health & Safety Manual
- Auditing the staff with regard to compliance with the Hazardous Waste Contingency Plan
- Contacting the hazardous waste subcontractors for review of procedures and opportunities for minimization of waste



4.3 DEPUTIES

The following table defines who assumes the responsibilities of key personnel in their absence:

Key Personnel	Deputy	Comment
Laboratory Director: Deborah Lowe	Project Technical Manager – Dave Dunlap	NELAP Technical Manager (entire laboratory)
Quality Assurance Manager: Virginia Zusman	Quality Assurance Specialist: Pam Dudeck	
Technical Director: Larry Matko	Laboratory Director: Deborah Lowe	NELAP Technical Manager (Lipids & 8141)
Organics Department Manager: Sharon Bacha	Designated Senior GC and GCMS Analyst	NELAP Technical Manager (Organics)
Inorganics Department Manager: Roseann Ruyechan	Designated Metals and Wet Chemistry Supervisors / Senior Analyst	NELAP Technical Manager (Inorganics, Inorganics-Non-metals)
Organic Prep Team Leader: Sharon Bacha/Larry Matko	Designated Senior Organic Prep Analyst	
Sample Management Department Manager: Christina Kovitch	Lab Director or Designated person in the Sample Management group	

If the NELAP Technical Manager is absent for a period of time exceeding 15 consecutive calendar days, the Laboratory Director must designate another full time staff member meeting the qualifications of the Technical Manager to temporarily perform this function. If the absence exceeds 30 consecutive calendar days, the primary accrediting authority must be notified in writing.

Figure 4-1 - Laboratory Organization Chart

Note: Organization Charts are subject to change - contact the laboratory for the most recent version

SECTION 5

QUALITY SYSTEM

5.1 Quality Policy Statement

It is Eurofins TestAmerica's Policy to provide the highest quality data achievable by:

- Reading and understanding all of the quality documents applicable to each position and implementing the process in our work.
- Following all recordkeeping requirements; describing clearly and accurately all activities performed; recording "real time" as the task is carried out; understanding that it is never acceptable to "back date" entries and should additional information be required at a later date, the actual date and by whom the notation is made must be documented.
- Ensuring data integrity through the completeness, consistency, impartiality and accuracy of the data generated. Data is attributable, legible, contemporaneously recorded, original or a true copy, and accurate (ALCOA). This applies to manual paper documentation and electronic records.
- Providing accountability and traceability for each sample analyzed through proper sample handling, labeling, preparation, instrument calibration/qualification/validation, analysis, and reporting; establishing an audit trail (the who, what, when, and why) that identifies date, time, analyst, instrument used, instrument conditions, quality control samples (where appropriate and/or required by the method), and associated standard material.
- Emphasizing a total quality management process which provides impartiality, accuracy, and strict compliance with agency regulations and client requirements, giving the highest degree of confidence; understanding that meeting the requirements of the next employee in the work flow process is just as important as meeting the needs of the external client.
- Providing thorough documentation and explanation to qualify reported data that may not meet all requirements and specifications, but is still of use to the client; understanding this occurs only after discussion with the client on the data limitations and acceptability of this approach.
- Responding immediately to indications of questionable data, out-of-specification occurrences, equipment malfunctions, and other types of laboratory problems, with investigation and applicable corrective action; documenting these activities completely, including the reasons for the decisions made.
- Providing a work environment that ensures accessibility to all levels of management and encourages questions and expression of concerns on quality issues to management. Eurofins recognizes that the implementation of a quality assurance program requires management's commitment and support as well as the involvement of the entire staff
- Continually improve systems and manage risk to support quality improvement efforts in laboratory, administrative and managerial activities
- We each take personal responsibility to provide this quality product while meeting the company's high standards of integrity and ethics, understanding that improprieties, such as failure to conduct the required test, manipulation of test procedures or data, or inaccurate documentation will not be tolerated. Intentional misrepresentation of the activities performed is considered fraud and is grounds for termination.
- Provide data of known quality to its clients by adhering to approved methodologies, regulatory requirements and the QA/QC protocols.

❖ To comply with the ISO/IEC 17025:2017(E) International Standard, the 2009 and 2016 TNI Standards and to continually improve the effectiveness of the management system.

Every staff member at the laboratory plays an integral part in quality assurance and is held responsible and accountable for the quality of their work. It is, therefore, required that all laboratory personnel are trained and agree to comply with applicable procedures and requirements established by this document.

5.2 Ethics And Data Integrity

Eurofins TestAmerica is committed to ensuring the integrity of its data and meeting the quality needs of its clients. The elements of Eurofins TestAmerica's Ethics and Data Integrity Program include:

- An Ethics Policy (Corporate Policy No. CW-L-P-004) and Employee Ethics Statements
- Ethics and Compliance Officers (ECOs)
- A Training Program
- Self-governance through disciplinary action for violations
- A Confidential mechanism for anonymously reporting alleged misconduct and a means for conducting internal investigations of all alleged misconduct. (Corporate SOP No. CW-L-S-002)
- Procedures and guidance for recalling data if necessary (Corporate SOP No. CW-Q-S-005)
- Effective external and internal monitoring system that includes procedures for internal audits (Section 15 and laboratory SOP PT-QA-002 on Internal Auditing)
- Produce results, which are accurate and include QA/QC information that meets client pre-defined Data Quality Objectives (DQOs)
- Present services in a confidential, honest and forthright manner
- Provide employees with guidelines and an understanding of the Ethical and Quality Standards of our Industry
- Provide procedures and guidance to ensure the impartiality and confidentiality of all data and customer information.
- Operate our facilities in a manner that protects the environment and the health and safety of employees and the public
- Obey all pertinent federal, state and local laws and regulations and encourage other members of our industry to do the same
- Educate clients as to the extent and kinds of services available
- Assert competency only for work for which adequate personnel and equipment are available and for which adequate preparation has been made
- Promote the status of environmental laboratories, their employees, and the value of services rendered by them

5.3 Quality System Documentation

The laboratory's Quality System is communicated through a variety of documents.

- Quality Assurance Manual – Each laboratory has a lab specific quality assurance manual.
- Corporate SOPs and Policies - Corporate SOPs and Policies are developed for use by all relevant laboratories. They are incorporated into the laboratory's normal SOP distribution, training and tracking system. Corporate SOPs may be general or technical.

- Work Instructions - A subset of procedural steps, tasks or forms associated with an operation of a management system (e.g., checklists, preformatted bench sheets, forms).
- Laboratory SOPs – General and Technical
- Laboratory QA/QC Policy Memorandums

5.3.1 Order of Precedence

In the event of a conflict or discrepancy between policies, the order of precedence is as follows:

- Corporate Quality Management Plan (CQMP)
- Corporate SOPs and Policies
- Laboratory QA/QC Policy Memorandum
- Laboratory Quality Assurance Manual (QAM)
- Laboratory SOPs and Policies
- Other (Work Instructions (WI), memos, flow charts, etc.)

Note: The laboratory has the responsibility and authority to operate in compliance with regulatory requirements of the jurisdiction in which the work is performed. Where the CQMP conflicts with those regulatory requirements, the regulatory requirements of the jurisdiction shall hold primacy. The laboratory's QAM shall take precedence over the CQMP in those cases.

5.4 QA/QC Objectives For The Measurement Of Data

Quality Assurance (QA) and Quality Control (QC) are activities undertaken to achieve the goal of producing data that accurately characterize the sites or materials that have been sampled. Quality Assurance is generally understood to be more comprehensive than Quality Control. Quality Assurance can be defined as the integrated system of activities that ensures that a product or service meets defined standards.

Quality Control is generally understood to be limited to the analyses of samples and to be synonymous with the term *"analytical quality control"*. QC refers to the routine application of statistically based procedures to evaluate and control the accuracy of results from analytical measurements. The QC program includes procedures for estimating and controlling precision and bias and for determining reporting limits.

Request for Proposals (RFPs) and Quality Assurance Project Plans (QAPP) provide a mechanism for the client and the laboratory to discuss the data quality objectives in order to ensure that analytical services closely correspond to client needs. In order to ensure the ability of the laboratory to meet the Data Quality Objectives (DQOs) specified in the QAPP, clients are advised to allow time for the laboratory to review the QAPP before being finalized. The client is responsible for developing the QAPP, however, the laboratory will provide support to the client for developing the sections of the QAPP that concern laboratory activities.

Historically, laboratories have described their QC objectives in terms of precision, accuracy, representativeness, comparability, completeness, selectivity and sensitivity.

5.4.1 Precision

The laboratory objective for precision is to meet the performance for precision demonstrated for the methods on similar samples and to meet data quality objectives of the EPA and/or other

regulatory programs. Precision is defined as the degree of reproducibility of measurements under a given set of analytical conditions (exclusive of field sampling variability). Precision is documented on the basis of replicate analysis, usually duplicate or matrix spike (MS) duplicate samples.

5.4.2 Accuracy

The laboratory objective for accuracy is to meet the performance for accuracy demonstrated for the methods on similar samples and to meet data quality objectives of the EPA and/or other regulatory programs. Accuracy is defined as the degree of bias in a measurement system. Accuracy may be documented through the use of laboratory control samples (LCS) and/or MS. A statement of accuracy is expressed as an interval of acceptance recovery about the mean recovery.

5.4.3 Representativeness

The laboratory objective for representativeness is to provide data which is representative of the sampled medium. Representativeness is defined as the degree to which data represent a characteristic of a population or set of samples and is a measurement of both analytical and field sampling precision. The representativeness of the analytical data is a function of the procedures used in procuring and processing the samples. The representativeness can be documented by the relative percent difference between separately procured, but otherwise identical samples or sample aliquots.

The representativeness of the data from the sampling sites depends on both the sampling procedures and the analytical procedures. The laboratory may provide guidance to the client regarding proper sampling and handling methods in order to assure the integrity of the samples.

5.4.4 Comparability

The comparability objective is to provide analytical data for which the accuracy, precision, representativeness and reporting limit statistics are similar to these quality indicators generated by other laboratories for similar samples, and data generated by the laboratory over time.

The comparability objective is documented by inter-laboratory studies carried out by regulatory agencies or carried out for specific projects or contracts, by comparison of periodically generated statements of accuracy, precision and reporting limits with those of other laboratories.

5.4.5 Completeness

The completeness objective for data is 90% (or as specified by a particular project), expressed as the ratio of the valid data to the total data over the course of the project. Data will be considered valid if they are adequate for their intended use. Data usability will be defined in a QAPP, project scope or regulatory requirement. Data validation is the process for reviewing data to determine its usability and completeness. If the completeness objective is not met, actions will be taken internally and with the data user to improve performance. This may take the form of an audit to evaluate the methodology and procedures as possible sources for the difficulty or may result in a recommendation to use a different method.

5.4.6 Selectivity

Selectivity is defined as: The capability of a test method or instrument to respond to a target substance or constituent in the presence of non-target substances. Target analytes are separated from non-target constituents and subsequently identified/detected through one or more of the following, depending on the analytical method: extractions (separation), digestions (separation), interelement corrections (separation), use of matrix modifiers (separation), specific retention times (separation and identification), confirmations with different columns or detectors (separation and identification), specific wavelengths (identification), specific mass spectra (identification), specific electrodes (separation and identification), etc..

5.4.7 Sensitivity

Sensitivity refers to the amount of analyte necessary to produce a detector response that can be reliably detected (above the Method Detection Limit) or quantified (above the Reporting Limit).

5.5 Criteria For Quality Indicators

The laboratory maintains tables, housed in TALS, that summarizes the precision and accuracy acceptability limits for analyses performed at Eurofins TestAmerica Pittsburgh. This summary includes an effective date, is updated each time new limits are generated and is managed by the laboratory's QA department. Limits are archived within the LIMS when replaced. Unless otherwise noted, limits within these tables are laboratory generated. Some acceptability limits are derived from US EPA methods when they are required. Where US EPA method limits are not required, the laboratory has developed limits from evaluation of data from similar matrices. Criteria for development of control limits are contained in laboratory SOP PT-QA-021, *Laboratory Quality Control Program*.

5.6 Statistical Quality Control

Statistically-derived precision and accuracy limits are required by selected methods (such as SW-846) and programs. The laboratory routinely utilizes statistically-derived limits to evaluate method performance and determine when corrective action is appropriate. Analysts are restricted to using only the current limits within TALS, controlled as discussed above. The Quality Assurance department maintains an archive of all limits used within the laboratory. These limits are maintained in TALS as part of the analytical historical record. If a method defines the QC limits, the method limits are used. For further details refer to laboratory SOP PT-QA-021.

If a method, or program, defines the QC limits, the required limits are used, unless laboratory developed limits are tighter.

If a method requires the generation of historical limits, the lab develops such limits from recent data in the QC database of TALS following the guidelines described in Section 24 and laboratory SOP PT-QA-021. All calculations and limits are documented and dated when approved and effective. On occasion, a client may request contract-specified limits for a specific project.

Current QC limits are entered and maintained in TALS analyte database. As sample results and the related QC are entered into TALS the sample QC values are compared with the limits in TALS to determine if they are within the acceptable range. The analyst then evaluates if the

sample needs to be rerun or re-extracted/rerun or if a comment should be added to the report explaining the reason for the QC outlier.

5.6.1 QC Charts

The generation and use of QC Charts (Control Charts) are described in laboratory SOP PT-QA-021. The QA department evaluates control charts to determine if adjustments need to be made to existing limits or corrective actions are necessary. All findings are documented and kept on file.

5.7 Quality System Metrics

In addition to the QC parameters discussed above, the entire Quality System is evaluated on a monthly basis through the use of specific metrics (refer to Section 16). These metrics are used to drive continuous improvement in the laboratory's Quality System.

5.8 Laboratory Certification/Accreditation

The Laboratory Quality System is designed to meet the requirements of all governing bodies through which it holds certification / accreditation.

- A list of certifications and accredited scopes is maintained by the QA Department, and current certificates are posted in the laboratory lobby. Expired certificates are maintained in the QA archive.
- Certification renewal is completed on an annual basis, or within the time frame required by each accrediting agency.
- The laboratory shall read and follow all accrediting agencies' accreditation requirements before applying and when renewing accreditations.
- The laboratory indicates clearly in its reports which certifications it holds,
- The laboratory does not use their NELAP or any state certificate of accreditation, accreditation status, or accrediting agency logo to imply endorsement by any accrediting body.
- The laboratory distinguishes on data reports between testing for which the laboratory is accredited and testing for which the laboratory is not accredited. The laboratory's primary AB accreditation number is also included on all data reports.
- Upon expiration, suspension, revocation or voluntary relinquishment of accreditation, a laboratory shall:
  - Discontinue use of all catalogs, advertising, business solicitations, proposals, quotations, laboratory analytical results or other materials that contain reference to the laboratory's past accreditation status.
  - Discontinue use or display of the Department's logo.
  - Return unexpired certificates of accreditation to the Department within 48 hours.
  - Discontinuing all testing for the affected fields of accreditation.
  - Notify all customers affected by the loss or suspension in writing within 72 hours of receiving notice of the change in accreditation status.

- If there is a change in laboratory ownership, the laboratory must notify all accreditors within 10 days. Some accrediting agencies require additional change applications be submitted within 30 days.

SECTION 6

DOCUMENT CONTROL

6.1 Overview

The QA Department is responsible for the control of documents used in the laboratory to ensure that approved, up-to-date documents are in circulation and out-of-date (obsolete) documents are archived or destroyed. The following documents, at a minimum, must be controlled:

- Laboratory Quality Assurance Manual
- Laboratory Standard Operating Procedures (SOP)
- Laboratory Policies
- Work Instructions and Forms
- Logbooks and Calculation Spreadsheets
- Corporate Policies and Procedures distributed outside the intranet
- External documents that are used as part of the laboratory's Quality System

The Corporate QA Department posts Corporate Manuals, SOPs, Policies, Work Instructions, White Papers and Training Materials on the company intranet site. These Corporate documents are only considered controlled when they are read on the intranet site. Printed copies are considered uncontrolled unless the laboratory physically distributes them as controlled documents. A detailed description of the procedure for issuing, authorizing, controlling, distributing, and archiving Corporate documents is found in Corporate SOP No. CW-Q-S-001, *Corporate Document Control and Archiving*. The laboratory's internal document control procedure is defined in laboratory SOP PT-QA-010, *Document Development and Control*.

The laboratory QA Department also maintains access to various references and document sources integral to the operation of the laboratory. This includes reference methods and regulations. Instrument manuals (hard or electronic copies) are also maintained by the laboratory.

The laboratory maintains control of records for raw analytical data and supporting records such as audit reports and responses, logbooks, standard logs, training files, MDL studies, Proficiency Testing (PT) studies, certifications and related correspondence, and corrective action reports and Nonconformance Memos (NCMs). Raw analytical data consists of bound logbooks, instrument printouts, any other notes, magnetic media, electronic data and final reports.

6.2 Document Approval And Issue

The pertinent elements of a document control system for each document include a unique document title and number, pagination, the total number of pages of the item or an 'end of document' page, the effective date, revision number and the laboratory's name. The QA personnel are responsible for the maintenance of this system.

Controlled documents are authorized by the QA Department. In order to develop a new document, a responsible manager submits an electronic or paper draft to the QA Department for suggestions and approval before use. Upon approval, QA personnel add the identifying version information to the document and retain that document as the official document on file. That document is then provided to all applicable operational units. Controlled documents are

identified as such and records of their distribution are kept by the QA Department. Document control may be achieved by either electronic or hardcopy distribution.

The QA Department maintains a list of the official versions of controlled documents.

Quality System Policies and Procedures will be reviewed at a minimum of every two years, or more often as required, and revised as appropriate. Changes to documents occur when a procedural change warrants.

6.3 Procedures For Document Control Policy

For creation of or changes to SOPs and QA manual, refer to Corporate SOP No. CW-Q-S-002, *Writing a Standard Operating Procedure (SOP)* and laboratory SOP No. PT-QA-010.

Uncontrolled copies must not be used within the laboratory. Controlled documents are marked as such, and posted to a controlled laboratory access drive by the QA department. Controlled distribution is achieved electronically. Controlled hardcopies must be obtained through the QA Department. Previous revisions and back-up data are stored on a restricted access drive by the QA department. Details of the numbering system, required format, and controlled distribution of documents are described in laboratory SOP No. PT-QA-010. Editable copies are stored on a restricted access drive.

Forms, worksheets, work instructions and information are organized by department by the QA office. Controlled electronic versions are distributed through the intranet and hard copies can be printed out as needed. Editable versions are stored on a restricted access drive. All forms used in the laboratory are tracked in the controlled documents database which can be accessed by the QA department and the IT group. The procedure for the care of these documents is in laboratory SOP No. PT-QA-010.

6.4 Obsolete Documents

All invalid or obsolete documents are removed from general laboratory access, or otherwise prevented from unintended use. The laboratory has specific procedures as described above to accomplish this. Obsolete hardcopy documents are collected from employees according to distribution lists and are destroyed. At least one electronic copy of the obsolete document is archived according to laboratory SOP No. PT-QA-019, *Records Information Management*.

SECTION 7

SERVICE TO THE CLIENT

7.1 Overview

The laboratory has established procedures for the review of work requests and contracts, oral or written. The procedures include evaluation of the laboratory's capability and resources to meet the contract's requirements within the requested time period. All requirements, including the methods to be used, must be adequately defined, documented and understood. For many environmental sampling and analysis programs, testing design is site or program specific and does not necessarily fit into a standard laboratory service or product. It is the laboratory's intent to provide both standard and customized environmental laboratory services to our clients.

A thorough review of technical and QC requirements contained in contracts is performed to ensure project success. The appropriateness of requested methods, and the lab's capability to perform them must be established. Projects, proposals and contracts are reviewed for adequately defined requirements and the laboratory's capability to meet those requirements. Alternate test methods that are capable of meeting the clients' requirements may be proposed by the lab. A review of the lab's capability to analyze non-routine analytes is also part of this review process.

All projects, proposals and contracts are reviewed for the client's requirements in terms of compound lists, test methodology requested, sensitivity (detection and reporting levels), accuracy, and precision requirements (%Recovery and RPD). The reviewer ensures that the laboratory's test methods are suitable to achieve these requirements and that the laboratory holds the appropriate certifications and approvals to perform the work. The laboratory and any potential subcontract laboratories must be certified, as required, for all proposed tests.

The laboratory must determine if it has the necessary physical, personnel and information resources to meet the contract, and if the personnel have the expertise needed to perform the testing requested. Each proposal is checked for its impact on the capacity of the laboratory's equipment and personnel. As part of the review, the proposed turnaround time will be checked for feasibility.

Electronic or hard copy deliverable requirements are evaluated against the laboratory's capacity for production of the documentation.

If the laboratory cannot provide all services but intends to subcontract such services, whether to another Eurofins TestAmerica facility or to an outside firm, this will be documented and discussed with the client prior to contract approval. (Refer to Section 8 for Subcontracting Procedures.)

The laboratory informs the client of the results of the review if it indicates any potential conflict, deficiency, lack of accreditation, or inability of the lab to complete the work satisfactorily. Any discrepancy between the client's requirements and the laboratory's capability to meet those requirements is resolved in writing before acceptance of the contract. It is necessary that the contract be acceptable to both the laboratory and the client. Amendments initiated by the client and/or Eurofins TestAmerica, are documented in writing.

All contracts, QAPPs, Sampling and Analysis Plans (SAPs), contract amendments, and documented communications become part of the project record.

The same contract review process used for the initial review is repeated when there are amendments to the original contract by the client, and the participating personnel are informed of the changes.

7.2 Review Sequence And Key Personnel

Appropriate personnel will review the work request at each stage of evaluation.

For routine projects and other simple tasks, a review by the Project Manager (PM) is considered adequate. The PM confirms that the laboratory has any required certifications, that it can meet the clients' data quality and reporting requirements and that the lab has the capacity to meet the clients turn around needs. It is recommended that, where there is a sales person assigned to the account, an attempt should be made to contact that sales person to inform them of the incoming samples.

For new, complex or large projects, the proposed contract is given to the Client Relationship Manager or Proposal Team, who will decide which lab will receive the work based on the scope of work and other requirements, including certification, testing methodology, and available capacity to perform the work. The contract review process is outlined in Eurofins TestAmerica's Corporate Policy No. CA-L-P-002**,** *Contract Compliance Policy*.

This review encompasses all facets of the operation. The scope of work is distributed to the appropriate personnel, as needed based on scope of contract, to evaluate all of the requirements shown above (not necessarily in the order below):

- Contract Administrator
- VP of Operations
- Laboratory Project Management
- Laboratory Director / Technical Manager
- Laboratory and/or Corporate Quality
- Laboratory and/or Corporate EH&S
- The laboratory Director reviews the formal laboratory quote and makes final acceptance for their facility.

The Sales Director, Contract Administrator, Account Executive or Proposal Coordinator then submits the final proposal to the client.

In the event that one of the above personnel is not available to review the contract, his or her back-up will fulfill the review requirements.

7.3 Documentation

The Contracts Department maintains copies of all signed contracts. In the Pittsburgh laboratory, copies of contracts are maintained in the laboratory network public drive by the sales/marketing personnel.

Appropriate records are maintained for every contract or work request. All stages of the contract review process are documented and include records of any significant changes. Contracts review documentation and is maintained in the network public drive.

The contract will be distributed to and maintained by the appropriate sales/marketing personnel and the Account Manager. A copy of the contract and formal quote will be filed with the laboratory PM and the Lab Director.

Records are maintained of pertinent discussions with a client relating to the client's requirements or the results of the work during the period of execution of the contract. The PM keeps a phone log or an electronic record of conversations with the client.

7.3.1 Project-Specific Quality Planning

Communication of contract specific technical and QC criteria is an essential activity in ensuring the success of site specific testing programs. To achieve this goal, a PM is assigned to each client. It is the PM's responsibility to ensure that project-specific technical and QC requirements are effectively evaluated and communicated to the laboratory personnel before and during the project. QA department involvement may be needed to assist in the evaluation of custom QC requirements.

PM's are the primary client contact and they ensure resources are available to meet project requirements. Although PM's do not have direct reports or staff in production, they coordinate opportunities and work with laboratory management and supervisory staff to ensure available resources are sufficient to perform work for the client's project. Project management is positioned between the client and laboratory resources.

Prior to work on a new project, the dissemination of project information and/or project opening meetings may occur to discuss schedules and unique aspects of the project. Items to be discussed may include the project technical profile, turnaround times, holding times, methods, analyte lists, reporting limits, deliverables, sample hazards, or other special requirements. The PM introduces new projects to the laboratory staff through project kick-off meetings or to the supervisory staff during production meetings. These meetings provide direction to the laboratory staff in order to maximize production and client satisfaction, while maintaining quality. In addition, project notes may be associated with each sample batch as a reminder upon sample receipt and analytical processing.

During the project, any change that may occur within an active project is agreed upon between the client/regulatory agency and the PM/laboratory. These changes (e.g., use of a non-standard method or modification of a method) and approvals must be documented prior to implementation. Documentation pertains to any document, e.g., letter, e-mail, variance, contract addendum, which has been signed by both parties.

Such changes are also communicated to the laboratory during production and operations meetings. Such changes are updated to the project notes and are introduced to the managers at

these meetings. The laboratory staff is then introduced to the modified requirements via the PM or the individual laboratory Technical Manager. After the modification is implemented into the laboratory process, documentation of the modification is made in the case narrative of the data report(s).

The laboratory strongly encourages client visits to the laboratory and for formal/informal information sharing session with employees in order to effectively communicate ongoing client needs as well as project specific details for customized testing programs.

7.4 Special Services

The laboratory cooperates with clients and their representatives to monitor the laboratory's performance in relation to work performed for the client. It is the laboratory's goal to meet all client requirements in addition to statutory and regulatory requirements. The laboratory has procedures to ensure confidentiality to clients (Section 25).

The laboratory's standard procedures for reporting data are described in Section 25. Special services are also available and provided upon request. These services include:

- Reasonable access for our clients or their representatives to the relevant areas of the laboratory for the witnessing of tests performed for the client
- Assist client-specified third party data validators as specified in the client's contract
- Supplemental information pertaining to the analysis of their samples

  Note: An additional charge may apply for additional data/information that was not requested prior to the time of sample analysis or previously agreed upon.

When the client requests a statement of conformity to a specification or standard based on the analysis performed by the laboratory (e.g., pass/fail, in-tolerance/out-of-tolerance), the decision rule shall be clearly defined. Unless inherent in the requested specification or standard, the decision rule selected shall be communicated to the client. Associated reporting requirements are addressed in Section 25.2.18.

7.5 Client Communication

Project managers are the primary communication link to the clients. They shall inform their clients of any delays in project completion as well as any non-conformances in either sample receipt or sample analysis. Project management will maintain ongoing client communication throughout the entire client project.

Technical Managers, or their designees, are available to discuss any technical questions or concerns that the client may have.

7.6 Reporting

The laboratory works with our clients to produce any special communication reports required by the contract.

To the extent possible, results of testing or analysis of environmental samples shall be reported only if all quality control, analytical testing and sample acceptance measures are acceptable. If a quality control, analytical testing or sample acceptance measure is

found to be out of control and the results of the testing or analysis of environmental samples are to be reported, all environmental samples associated with the failed quality control measure shall be documented and the results flagged in an unambiguous manner on the sample analysis report with the appropriate data qualifiers.

7.7 Client Surveys

The laboratory assesses both positive and negative client feedback. The results are used to improve overall laboratory quality and client service. Eurofins TestAmerica's Sales and Marketing teams periodically develops lab and client specific surveys to assess client satisfaction. Survey results and both complaints and compliments are tracked in the monthly quality metrics report.

SECTION 8

SUBCONTRACTING OF TESTS

8.1 Overview

For the purpose of this quality manual, the phrase subcontract laboratory refers to a laboratory external to the Eurofins TestAmerica laboratories. To distinguish between an external laboratory and a Eurofins TestAmerica laboratory at a different location, the phrase "work sharing" or "work share lab" refers to internal subcontracting between Eurofins TestAmerica laboratories. The term outsourcing refers to the act of subcontracting tests.

When contracting with our clients, the laboratory makes commitments regarding the services to be performed and the data quality for the results to be generated. When the need arises to outsource testing for our clients because project scope, changes in laboratory capabilities, capacity or unforeseen circumstances, we must be assured that the subcontractors or work sharing laboratories understand the requirements and will meet the same commitments we have made to the client. Refer to Corporate SOP No. CA-L-S-004, *Subcontracting*, and CA-C-S-001, *Worksharing Process*.

When outsourcing analytical services, the laboratory will assure, that the subcontract or work sharing laboratory maintains a program consistent with the requirements of this document, the requirements specified in TNI/ISO 17025 and/or the client's Quality Assurance Project Plan (QAPP). All QC guidelines specific to the client's analytical program are transmitted to the subcontractor or work share lab and agreed upon before sending the samples to the subcontract facility. Additionally, work requiring accreditation will be placed with an appropriately accredited laboratory. The laboratory performing the subcontracted work will be identified in the final report, as will non-TNI accredited work where required.

Project Managers (PMs) and Account Executives (AE) for the Export Lab (i.e. the Eurofins TestAmerica laboratory that transfers samples to another laboratory) are responsible for obtaining client approval prior to subcontracting or work sharing any samples. The laboratory will advise the client of a subcontract arrangement in writing and when possible approval from the client shall be obtained and retained in the project folder. These approvals may be granted by the client in written contractual agreements between the client and Eurofins TestAmerica.

Note: In addition to the client, some regulating agencies, (e.g, USDA) or contracts may require notification prior to placing such work**.** Client notification and approval must be documented.

8.2 Qualifying And Monitoring Subcontractors

Whenever a PM, Account Executive (AE) or Customer Service Manager (CSM) becomes aware of a client requirement or laboratory need where samples must be outsourced to another laboratory, the other laboratory(s) shall be selected based on the following:

- Subcontractors specified by the client – In these circumstances, the client assumes responsibility for the quality of the data generated from the use of a subcontractor.
- Subcontractors reviewed by Eurofins TestAmerica – Firms which have been reviewed by the company and are known to meet standards for accreditations (e.g. State, TNI); technical specifications; legal and financial information.

A list of approved vendors is available on the Eurofins TestAmerica intranet site. Approved vendors' capabilities and certifications are found in the individual folders maintained on that site.

All Eurofins TestAmerica laboratories are pre-qualified for work sharing provided they hold the appropriate accreditations and can adhere to the project/program requirements. The originating laboratory is responsible for communicating all technical, quality, and deliverable requirements as well as other contract needs. (See Corporate SOP No. CA-C-S-001, *Work Sharing Process*, for details).

8.2.1 When the potential sub-contract laboratory has not been previously approved, Account Executives or PMs may nominate a laboratory as a subcontractor based on need. The decision to nominate a laboratory must be approved by the Client Relations Manager (CRM) or Laboratory Director. The CRM or Laboratory Director requests that the QA Manager or Project Manager begin the process of approving the subcontract laboratory as outlined in Corporate SOP No. CA-L-S-004, Subcontracting. The client must provide acknowledgement that the samples can be sent to that facility (an e-mail is sufficient documentation or if acknowledgement is verbal, the date, time, and name of person providing acknowledgement must be documented).

Once the appropriate accreditation and legal information is received by the laboratory, it is evaluated for acceptability and forwarded to the Corporate Quality Information Manager (QIM) for review. After the Corporate QIM reviews the documents for completeness, the information is forwarded to the Finance Department for formal signature and contracting with the laboratory. The approved vendor will be added to the approved subcontractor list on the intranet site and the finance group is concurrently notified.

The client will assume responsibility for the quality of the data generated from the use of a subcontractor they have requested the lab to use. The qualified subcontractors on the intranet site are known to meet minimal standards. Eurofins TestAmerica does not certify laboratories. The subcontractor is on our approved list and can only be recommended to the extent that we would use them.

8.3 Oversight and Reporting

8.3.1 The status and performance of qualified subcontractors will be monitored periodically by the Corporate Quality department and includes an annual review process (see Subcontracting SOP CW-L-S-004). Any problems identified will be brought to the attention of Eurofins TestAmerica's Corporate Finance, Legal or Corporate Quality personnel.

- Complaints shall be investigated. Documentation of the complaint, investigation and

corrective action will be maintained in the subcontractor's file on the intranet site. Complaints are posted using the Vendor Performance Report.

- Information shall be updated on the intranet when new information is received from the subcontracted laboratories.
- Subcontractors in good standing will be retained on the intranet listing. CSO personnel will notify all Eurofins TestAmerica laboratories, Corporate Quality and Corporate Contracts if any laboratory requires removal from the intranet site. This notification will be posted on the intranet site and e-mailed to all CSO personnel, Laboratory Directors, QA Managers, and Sales Personnel.

Prior to initially sending samples to the subcontracted laboratory, the PM confirms their certification status to determine if it's current and scope-inclusive. The information is documented within the project records.

8.3.2 For continued use of an approved external subcontractor, current certifications are viewed by the responsible Project Manager on the intranet site. For Eurofins TestAmerica laboratories, certifications can be viewed on through TALS.

8.3.3 All subcontracted samples must be accompanied by a Eurofins TestAmerica Chain of Custody (COC). A copy of the original COC sent by the client must be available in TALS for all samples workshared within Eurofins TestAmerica. Client COCs are only forwarded to external subcontractors when samples are shipped directly from the project site to the subcontractor lab. Under routine circumstances, client COCs are not provided to external subcontractors.

Through communication with the subcontracted laboratory, the PM monitors the status of the subcontracted analyses, facilitates successful execution of the work, and ensures the timeliness and completeness of the analytical report.

Non-TNI accredited work must be identified in the subcontractor's report as appropriate. If TNI accreditation is not required, the report does not need to include this information.

Reports submitted from subcontractor laboratories are not altered and are included in their original form in the final project report. This clearly identifies the data as being produced by a subcontractor facility. If subcontract laboratory data is incorporated into the laboratories EDD (i.e., imported), the report must explicitly indicate which lab produced the data for which methods and samples.

Note: The results submitted by a Eurofins TestAmerica work sharing laboratory may be transferred electronically and the results reported by the Eurofins TestAmerica work sharing lab are identified on the final report. The report must explicitly indicate which lab produced the data for which methods and samples. The final report must include a copy of the completed COC for all work sharing reports.

If a report including workshare data is sent to West Virginia clients, then individual reports per laboratory must be generated.

Note: If samples are subcontracted for SDWA compliance testing, the following information must be provided to the subcontract laboratory along with all other required chain-of-custody information: Public Water System ID Number and name of the system providing the sample, sample location ID number, and name and contact number of the Public Water System.

8.4 Contingency Planning

The full qualification of a subcontractor may be waived to meet emergency needs. This decision & justification must be documented in the project files, and the 'Purchase Order Terms And Conditions For Subcontracted Laboratory Services' must be sent with the samples and COC.

In the event this provision is utilized, the laboratory (e.g., PM) will be required to verify and document the applicable accreditations of the subcontractor. All other quality and accreditation requirements will still be applicable, but the subcontractor need not have signed a subcontract agreement with Eurofins TestAmerica at this time.

The use of any emergency subcontractor will require the PM to complete a JDE New Vendor Add Form in order to process payment to the vendor and add them to TALS. This form requires the user to define the subcontractor's category/s of testing and the reason for testing.

SECTION 9

PURCHASING SERVICES AND SUPPLIES

9.1 Overview

Evaluation and selection of suppliers and vendors is performed, in part, on the basis of the quality of their products, their ability to meet the demand for their products on a continuous and short term basis, the overall quality of their services, their past history, and competitive pricing. This is achieved through evaluation of objective evidence of quality furnished by the supplier, which can include certificates of analysis, recommendations, and proof of historical compliance with similar programs for other clients. To ensure that quality critical consumables and equipment conform to specified requirements, which may affect quality, all purchases from specific vendors are approved by a member of the supervisory or management staff. Capital expenditures are made in accordance with Eurofins TestAmerica's *Fixed Asset Acquisitions, Retention and Safeguarding* SOP No. CW-F-S-007.

Contracts will be signed in accordance with Eurofins TestAmerica's Corporate Policy No. CW-F-P-002, *Company-Wide Authorization Matrix*. Request for Proposals (RFP's) will be issued where more information is required from the potential vendors than just price. Process details are available in Eurofins TestAmerica's Corporate Policy No. CW-F-P-004, *Procurement and Contracts Policy*. RFP's allow Eurofins TestAmerica to determine if a vendor is capable of meeting requirements such as supplying all of the Eurofins TestAmerica facilities, meeting required quality standards and adhering to necessary ethical and environmental standards. The RFP process also allows potential vendors to outline any additional capabilities they may offer.

9.2 Glassware

Glassware used for volumetric measurements must be Class A or verified for accuracy according to laboratory procedure. Pyrex (or equivalent) glass should be used where possible. For safety purposes, thick-wall glassware should be used where available.

9.3 Reagents, Standards & Supplies

Purchasing guidelines for equipment and reagents must meet the requirements of the specific method and testing procedures for which they are being purchased. Solvents and acids are pre-

tested in accordance with Eurofins TestAmerica's Corporate SOP No. CA-Q-S-001, *Solvent & Acid Lot Testing and Approval Program*. Approval information for the solvents and acids tested under Corporate SOP No. CA-Q-S-001 is stored on the Eurofins TestAmerica intranet SharePoint, under Solvent Approvals. A master list of all tested materials, as well as the certificates of analysis for the materials, is stored in the same location. Additional approval and traceability instructions are found in laboratory SOP PT-QA-006, *Procurement of Standards and Materials; Labeling and Traceability*.

9.3.1 Purchasing

Chemical reagents, solvents, glassware, and general supplies are ordered as needed to maintain sufficient quantities on hand. Materials used in the analytical process must be of a known quality. The wide variety of materials and reagents available makes it advisable to specify recommendations for the name, brand, and grade of materials to be used in any determination. This information is contained in the method SOP. The analyst completes the Material Request Sheet when requesting reagents, standards, or supplies, or they may check the item out of the on-site consignment system that contains items approved for laboratory use.

If an item is not in the consignment system, the analyst must obtain approval from the area team leader/supervisor and Laboratory Director prior to the order being placed by the purchasing department. The responsible analyst places the order.

9.3.2 Receiving

It is the responsibility of the Sample Receiving department to receive the shipment. It is the responsibility of the analyst or manager who ordered the materials to document the date the materials were received. Once the ordered reagents or materials are received, the analyst or designee compares the information on the label or packaging to the original order to ensure that the purchase meets the quality level specified. This is documented through the addition of the received date and reviewers initials to the packing slip.

Lot numbers of solvents and acids are checked against the approved solvent/acid list. If the material is listed as unapproved, or is not listed, it is sequestered and returned to the vendor. Alternatively, the laboratory may test the material for the intended use, and if it is acceptable, document the approval on the approval list. Records of any testing performed locally are maintained by the QA department, and lots approvals and certificates of analysis are stored on the Eurofins TestAmerica intranet Pittsburgh SharePoint site.

Materials may not be released for use in the laboratory until they have been inspected, verified as suitable for use, and the inspection/verification has been documented.

Safety Data Sheets (SDSs) are available online through the Company's intranet website. Anyone may review these for relevant information on the safe handling and emergency precautions of on-site chemicals.

9.3.3 Specifications

Methods in use in the laboratory specify the grade of reagent that must be used in the procedure. If the quality of the reagent is not specified, analytical reagent grade will be used. It is the responsibility of the analyst to check the procedure carefully for the suitability of grade of reagent.

Chemicals must not be used past the manufacturer's expiration date and must not be used past the expiration time noted in a method SOP. If expiration dates are not provided, the laboratory may contact the manufacturer to determine an expiration date.

The laboratory assumes a five year expiration date on inorganic dry chemicals and solvents unless noted otherwise by the manufacturer or by the reference source method. Chemicals/solvents should not be used past the manufacturer's or SOPs expiration date unless verified as outlined below.

- An expiration date **cannot** be extended if the dry chemical/solvent is discolored or appears otherwise physically degraded. In this case, the dry chemical/solvent must be discarded.

- Expiration dates can be extended if the dry chemical/solvent is found to be satisfactory based on acceptable performance of quality control samples (Continuing Calibration Verification (CCV), Blanks, Laboratory Control Sample (LCS), etc.).

- If the dry chemical/solvent is used for the preparation of standards, the expiration dates can be extended 6 months if the dry chemical/solvent is compared to an unexpired independent source in performing the method and the performance of the dry chemical/solvent is found to be satisfactory. The comparison must show that the dry chemical/solvent meets CCV limits. The comparison studies are maintained on-file and available for review with each lab department and copy forwarded to QA department. Recertification is documented in TALS.

Wherever possible, standards must be traceable to national or international standards of measurement or to national or international reference materials. Records to that effect are available to the user.

Compressed gases in use are checked for pressure and secure positioning daily. To prevent a tank from going to dryness, or introducing potential impurities, the pressure should be closely watched as it decreases to approximately 15% of the original reading, at which point it should be replaced. For example, a standard sized laboratory gas cylinder containing 3,000 psig of gas should be replaced when it drops to approximately 500 psig. The quality of the gases must meet method or manufacturer specifications or be of a grade that does not cuase any analytical interference.

Water used in the preparation of samples, standards or reagents must have a specific conductivity of less than 1- µmho /cm (or specific resistivity of greater than 1.0 megohm-cm) at 25^{o}C. The specific conductivity is checked and recorded daily. If the water's specific conductivity is greater than the specified limit, the Facility Manager and appropriate Technical Managers/Supervisors must be notified immediately in order to notify all departments, decide on cessation (based on intended use) of activities, and make arrangements for correction.

The laboratory may purchase reagent grade (or other similar quality) water for use in the laboratory. This water must be certified clean by the supplier for all target analytes or otherwise verified by the laboratory prior to use. This verification is documented.

Standard lots are verified before first time use if the laboratory switches manufacturers or has historically had a problem with the type of standard.

Purchased bottleware used for sampling must be certified clean and the certificates must be maintained. If uncertified sampling bottleware is purchased, all lots must be verified clean prior to use. This verification must be maintained.

NOTE: Each bottleware type must be documented as clean down to the laboratory MDL for all target analytes for use with samples from Wisconsin.

Records of manufacturer's certification and traceability statements are maintained in files or binders in each laboratory section. These records include date of receipt, lot number (when applicable), and expiration date (when applicable). Incorporation of the item into the record indicates that the analyst has compared the new certificate with the previous one for the same purpose and that no difference is noted, unless approved and so documented by the Department Manager or QA Manager.

9.3.4 Storage

Reagent and chemical storage is important from the aspects of both integrity and safety. Light-sensitive reagents may be stored in brown-glass containers. Storage conditions are per the Corporate Environmental Health & Safety Manual (Corp. Doc. No. CW-E-M-001), method SOPs, or manufacturer instructions.

9.4 Purchase Of Equipment / Instruments / Software

When a new piece of equipment is needed, either for additional capacity or for replacing inoperable equipment, the analyst or supervisor makes a supply request to the Department Manager and/or the Laboratory Director. If they agree with the request, the procedures outlined in Corporate Policy No. CA-T-P-001, *Qualified Products List*, are followed. A decision is made as to which piece of equipment can best satisfy the requirements. The appropriate written requests are completed and purchasing places the order.

Upon receipt of a new or used piece of equipment, an identification name is assigned and added to the equipment list. IT must also be notified so that they can synchronize the instrument for back-ups. Its capability is assessed to determine if it is adequate or not for the specific application. For instruments, a calibration curve is generated, followed by MDLs, Demonstration of Capabilities (DOCs), and other relevant criteria (refer to Section 19).

For software, its operation must be deemed reliable and evidence of instrument verification must be retained by the IT Department. Software certificates supplied by the vendors are filed with the LIMS Administrator. The manufacturer's operation manual is retained in the laboratory in a designated area or near the instrument.

9.5 Services

Service to analytical instruments (except analytical balances) is performed on an as needed basis. Routine preventative maintenance is discussed in Section 20. The need for service is determined by analysts and/or Technical Managers. The service providers that perform the services are approved by the Laboratory or Technical Director.

Analytical balances are serviced and calibrated annually in accordance with laboratory SOP No. PT-QA-012, *Selection and Calibration of Balances and Weights*. The calibration and maintenance services are performed on-site, and the balances are returned to use immediately

following successful calibration. When the calibration certificates are received (usually within 24 hours of the service), they are reviewed, and documentation of the review is filed with the certificates. If the calibration was unsuccessful, the balance is immediately removed from service and segregated pending either further maintenance or disposal.

Calibration services for support equipment such as thermometers, weight sets, autopipettors, etc, are obtained from vendors with current and valid ISO 17025 accreditation for calibration of the specific piece of equipment. Prior to utilizing the vendor's services, the vendor's accreditation status is verified. Once the equipment has been calibrated, the calibration certificates are reviewed by the QA department, and documentation of the review is filed with the calibration certificates. The equipment is then returned to service within the laboratory.

9.6 Suppliers

Eurofins TestAmerica selects vendors through a competitive proposal / bid process, strategic business alliances or negotiated vendor partnerships (contracts). This process is defined in the Corporate Policy No. CW-F-P-004. The level of control used in the selection process is dependent on the anticipated spending amount and the potential impact on Eurofins TestAmerica business. Vendors that provide test and measuring equipment, solvents, standards, certified containers, instrument related service contracts or subcontract laboratory services shall be subject to more rigorous controls than vendors that provide off-the-shelf items of defined quality that meet the end use requirements. The purchasing system includes all suppliers/vendors that have been approved for use.

Evaluation of suppliers is accomplished by ensuring the supplier ships the product or material ordered and that the material is of the appropriate quality. This is documented by signing off on packing slips or other supply receipt documents. The purchasing documents contain the data that adequately describe the services and supplies ordered.

Any issues of vendor performance are to be reported immediately by the laboratory staff to the Corporate Purchasing Group by completing a Vendor Performance Report.

The Corporate Purchasing Group will work through the appropriate channels to gather the information required to clearly identify the problem and will contact the vendor to report the problem and to make any necessary arrangements for exchange, return authorization, credit, etc.

Suppliers are subject to re-evaluation, as deemed appropriate, through the use of Vendor Performance Reports used to summarize and review to determine corrective action necessary, or service improvements required by vendors.

The laboratory has access to a listing of all approved suppliers of critical consumables, supplies and services. This information is provided through the ORACLE purchasing system.

9.6.1 New Vendor Procedure

Eurofins TestAmerica employees who wish to request the addition of a new vendor must complete a Vendor Add Request Form.

New vendors are evaluated based upon criteria appropriate to the products or services provided as well as their ability to provide those products and services at a competitive cost. Vendors are also evaluated to determine if there are ethical reasons or potential conflicts of interest with Eurofins TestAmerica employees that would make it prohibitive to do business with them as well as their financial stability. The QA Department and/or the Technical Services Director are consulted with vendor and product selection that have an impact on quality.

SECTION 10

COMPLAINTS

10.1 Overview

The laboratory considers an effective client complaint handling processes to be of significant business and strategic value. Listening to and documenting client concerns captures client knowledge that enables our operations to continually improve processes and client satisfaction. An effective client complaint handling process also provides assurance to the data user that the laboratory will stand behind its data, service obligations and products.

A client complaint is any expression of dissatisfaction with any aspect of our business services (e.g., communications, responsiveness, data, reports, invoicing and other functions) expressed by any party, whether received verbally or in written form. Client inquiries, complaints or noted discrepancies are documented, communicated to management, and addressed promptly and thoroughly.

The laboratory has procedures for addressing both external and internal complaints with the goal of providing satisfactory resolution to complaints in a timely and professional manner.

The nature of the complaint is identified, documented and investigated, and an appropriate action is determined and taken. In cases where a client complaint indicates that an established policy or procedure was not followed, the QA Department must evaluate whether a special audit must be conducted to assist in resolving the issue. A written confirmation or letter to the client, outlining the issue and response taken is recommended as part of the overall action taken.

The process of complaint resolution and documentation utilizes the procedures outlined in Section 12 (Corrective Actions) and is documented following laboratory SOP PT-QA-016, *Non-Conformance and Corrective Action System*. A copy of this procedure will be made available to any interested party on request.

10.2 External Complaints

An employee that receives a complaint initiates the complaint resolution process by first documenting the complaint in the database, according to laboratory SOP PT-QA-016.

Complaints fall into two categories: correctable and non-correctable. An example of a correctable complaint would be one where a report re-issue would resolve the complaint. An example of a non-correctable complaint would be one where a client complains that their data was repeatedly late. Non-correctable complaints should be reviewed for preventive action measures to reduce the likelihood of future occurrence and mitigation of client impact.

The general steps in the complaint handling process are:

- Receiving and Documenting Complaints
- Acknowledge receipt of complaint, whenever possible
- Complaint Investigation and Service Recovery
- Process Improvement

The laboratory shall inform the initiator of the complaint of the results of the investigation and the corrective action taken, if any.

10.3 Internal Complaints

Internal complaints include, but are not limited to: errors and non-conformances, training issues, internal audit findings, and deviations from methods. Corrective actions may be initiated by any staff member who observes a nonconformance and shall follow the procedures outlined in Section 12. In addition, Corporate Management, Sales and Marketing and IT may initiate a complaint by contacting the laboratory or through the corrective action system described in Section 12.

10.4 Management Review

The number and nature of client complaints is reported by the QA Manager to the Laboratory Director and Quality Director in the QA Monthly report. Monitoring and addressing the overall level and nature of client complaints and the effectiveness of the solutions is part of the Annual Management Systems Review (Section 16).

SECTION 11

CONTROL OF NON-CONFORMING WORK

11.1 Overview

When data discrepancies are discovered or deviations and departures from laboratory SOPs, policies and/or client requests have occurred, corrective action is taken immediately. First, the laboratory evaluates the significance of the nonconforming work. Then, a corrective action plan is initiated based on the outcome of the evaluation. If it is determined that the nonconforming work is an isolated incident, the plan could be as simple as adding a qualifier to the final results and/or making a notation in the case narrative. If it is determined that the nonconforming work is a systematic or improper practices issue, the corrective action plan could include a more in depth investigation and a possible suspension of an analytical method. In all cases, the actions taken are documented using the laboratory's corrective action system (refer to Section 12).

Due to the frequently unique nature of environmental samples, sometimes departures from documented policies and procedures are needed. When an analyst encounters such a situation, the problem is presented to their manager for advice. The manager may elect to discuss it with the Laboratory Director or QA Manager or have a PM contact the client to decide on a logical course of action. Once an approach is agreed upon, the analyst documents it using the laboratories non-conformance/corrective action system described in Section 12. This information can then be supplied to the client in the form of a case narrative with the report.

Project Management may encounter situations where a client may request that a special procedure be applied to a sample that is not standard lab practice. Based on a technical evaluation, the lab may accept or opt to reject the request based on technical or ethical merit. An example might be the need to report a compound that the lab does not normally report. The lab would not have validated the method for this compound following the procedures in Section 19. The client may request that the compound be reported based only on the calibration. Such a request would need to be approved by the Laboratory Director and QA Manager, documented and included in the project folder. Deviations must also be noted on the final report with a statement that the compound is not reported in compliance with TNI (or the analytical method) requirements and the reason. Data being reported to a non-TNI state would need to note the change made to how the method is normally run.

11.2 Responsibilities And Authorities

Under certain circumstances, the Laboratory Director, a Technical Manager, or a member of the QA team may authorize departures from documented procedures or policies. The departures may be a result of procedural changes due to the nature of the sample; a one-time procedure for a client; QC failures with insufficient sample to reanalyze, etc. In most cases, the client will be informed of the departure prior to the reporting of the data. Any departures must be well documented using the laboratory's corrective action procedures. This information is documented on a Nonconformance Memo (NCM) and may also be documented in logbooks and/or data review checklists as appropriate. Any impacted data must be referenced in a case narrative and/or flagged with an appropriate data qualifier.

Any misrepresentation or possible misrepresentation of analytical data discovered by any laboratory staff member must be reported to facility Senior Management within 24-hours. The Senior Management staff is comprised of the Laboratory Director, the QA Manager, and the Technical Managers. The reporting of issues involving alleged violations of the company's Data Integrity or Manual Integration procedures must be conveyed to an ECO (e.g., the VP-QA/EHS) and the laboratory's Quality Director within 24 hours of discovery.

Whether an inaccurate result was reported due to calculation or quantitation errors, data entry errors, improper practices, or failure to follow SOPs, the data must be evaluated to determine the possible effect.

The Laboratory Director, QA Manager, ECOs, VP of Operations, and the Quality Directors have the authority and responsibility to halt work, withhold final reports, or suspend an analysis for due cause as well as authorize the resumption of work.

11.3 Evaluation Of Significance And Actions Taken

For each nonconforming issue reported, an evaluation of its significance and the level of management involvement needed is made. This includes reviewing its impact on the final data, whether or not it is an isolated or systematic issue, and how it relates to any special client requirements.

Corporate SOP entitled Data Recalls (CW-Q-S-005) is the procedure to be followed when it is discovered that erroneous or biased data may have been reported to clients or regulatory agencies.

Corporate SOP entitled Internal Investigations (CW-L-S-002) is the procedure to be followed for investigation and correction of situations involving alleged incidents of misconduct or violation of the company's ethics policy.

Laboratory level decisions are documented and approved using the laboratory's standard nonconformance/corrective action reporting in lieu of the data recall determination form contained in Eurofins TestAmerica's Corporate SOP No. CW-Q-S-005.

11.4 Prevention Of Nonconforming Work

If it is determined that the nonconforming work could recur, further corrective actions must be made following the laboratory's corrective action system. On at least a monthly basis, the QA Department evaluates non-conformances to determine if any nonconforming work has been repeated multiple times. If so, the laboratory's corrective action process must be followed.

11.5 Method Suspension/Restriction (Stop Work Procedures)

In some cases, it may be necessary to suspend/restrict the use of a method or target analyte which constitutes significant risk and/or liability to the laboratory. Suspension/restriction procedures can be initiated by any of the persons noted in Section 11.2, Paragraph 4.

Prior to suspension/restriction, confidentiality will be respected, and the problem with the required corrective and preventive action will be stated in writing and presented to the Laboratory Director.

The Laboratory Director shall arrange for the appropriate personnel to meet with the QA Manager as needed. This meeting shall be held to confirm that there is a problem, that suspension/restriction of the method is required and will be concluded with a discussion of the steps necessary to bring the method/target or test fully back on line. In some cases, that may not be necessary if all appropriate personnel have already agreed there is a problem and there is agreement on the steps needed to bring the method, target or test fully back on line. The QA Manager will also initiate a corrective action report as described in Section 12 if one has not already been started. A copy of any meeting notes and agreed upon steps should be e-mailed by the laboratory to the appropriate VP of Operations and member of Corporate QA. This e-mail acts as notification of the incident.

After suspension/restriction, the lab will hold all reports to clients pending review. No faxing, mailing or distributing through electronic means may occur. The report must not be posted for viewing on the internet. It is the responsibility of the Laboratory Director to hold all reporting and to notify all relevant laboratory personnel regarding the suspension/restriction (e.g., Project Management, Log-in, etc.). Clients will NOT generally be notified at this time. Analysis may proceed in some instances depending on the non-conformance issue.

Within 72 hours, the QA Manager will determine if compliance is now met and reports can be released, OR determine the plan of action to bring work into compliance, and release work. A team, with all principals involved (e.g., Laboratory Director, Technical Manager, QA Manager) can devise a start-up plan to cover all steps from client notification through compliance and release of reports. Project Management and the Directors of Client Services and Sales and Marketing must be notified if clients must be notified or if the suspension/restriction affects the laboratory's ability to accept work. The QA Manager must approve start-up or elimination of any restrictions after all corrective action is complete.

SECTION 12

CORRECTIVE ACTION

12.1 Overview

A major component of Eurofins TestAmerica's Quality Assurance (QA) Program is the problem investigation and feedback mechanism designed to keep the laboratory staff informed on quality related issues and to provide insight to problem resolution. When nonconforming work or departures from policies and procedures in the quality system or technical operations are identified, the corrective action procedure provides a systematic approach to assess the issues, restore the laboratory's system integrity, and prevent reoccurrence. Eurofins TestAmerica employs two systemsto manage non-conformances. Issues suspected of being systematic in nature and for which root cause analysis and a formal Corrective Action Report (CAR) are needed are documented in the Incident Corrective Action Tracking (ICAT) database. Routine batch non-conformances, events that are understood to be isolated in nature, are documented in the TALS non-conformance memo (NCM) system. See Figure 12-1 for an example CAR.

12.2 General

Problems within the quality system or within analytical operations may be discovered in a variety of ways, such as QC sample failures, internal or external audits, proficiency testing (PT) performance, client complaints, staff observation, etc.

The purpose of a corrective action system is to:

- Identify non-conformance events and assign responsibility(s) for investigating.
- Resolve non-conformance events and assign responsibility for any required corrective action.
- Identify systematic problems before they become serious.
- Identify and track client complaints and provide resolution.

12.2.1 Non-Conformance Memo (NCM) - is used to document the following types of corrective actions:

- Isolated deviations from an established procedure or SOP
- QC outside of limits (non-matrix related)
- Isolated reporting / calculation errors
- Client Complaints
- Discrepancies in materials / goods received vs. manufacturer packing slips (Forms of documentation other than NCMs in TALS are also acceptable.)
- Anomalies that occur during sample receipt, preparation or analysis

12.2.2 Corrective Action Documented in the ICAT Database

- Internal and external audit findings
- Failed or Unacceptable PT results
- Identified poor process or method performance trends
- Systematic reporting / calculation errors.

- Data recall investigations
- Questionable trends that are found in the review of NCMs
- Client complaints
- Excessive revised reports

The ICAT database is used to document background information, track the results of corrective action investigations and root cause analysis, and to provide reports of corrective action plans.

12.3 Closed Loop Corrective Action Process

Any employee in the company can initiate a corrective action. There are four main components to a closed-loop corrective action process once an issue has been identified: Cause Analysis, Selection and Implementation of Corrective Actions (both short and long term), Monitoring of the Corrective Actions, and Follow-up.

12.3.1 Cause Analysis

- Upon discovery of a non-conformance event, the event must be defined and documented. An entry into the ICAT system must be initiated. Someone is assigned to investigate the issue and the event is investigated for root cause. Table 12-1 provides some general guidelines on determining responsibility for assessment.
- The cause analysis step is the key to the process as a long term corrective action cannot be determined until the cause is determined.
- If the root cause is not readily obvious, the Technical Director, Laboratory Director, Technical Manager, or QA Manager (or QA designee) is consulted.

12.3.2 Selection and Implementation of Corrective Actions

- Where corrective action is needed, the laboratory shall identify potential corrective actions. The action(s) most likely to eliminate the problem and prevent recurrence are selected and implemented. Responsibility for implementation is assigned.
- Corrective actions shall be to a degree appropriate to the magnitude of the problem identified through the cause analysis.
- Whatever corrective action is determined to be appropriate, the laboratory shall document and implement the changes. The ICAT record is used for this documentation.

12.3.3 Root Cause Analysis

Root Cause Analysis is a class of problem solving (investigative) methods aimed at identifying the basic or causal factor(s) that underlie variation in performance or the occurrence of a significant failure. The root cause may be buried under seemingly innocuous events, many steps preceding the perceived failure. At first glance, the immediate response is typically directed at a symptom and not the cause. Typically, root cause analysis would be best with three or more incidents to triangulate a weakness. Corporate SOP No. CA-Q-S-009, *Root Cause Analysis*, describes this procedure.

Systematically analyze and document the root causes of the more significant problems that are reported. Identify, track, and implement the corrective actions required to reduce the likelihood

of recurrence of significant incidents. Trend the root cause data from these incidents to identify root causes that, when corrected, can lead to dramatic improvements in performance by eliminating entire classes of problems.

Identify the one event associated with problem and ask why this event occurred. Brainstorm the root causes of failures; for example, by asking why events occurred or conditions existed; and then why the cause occurred 5 consecutive times until you get to the root cause. For each of these sub events or causes, ask why it occurred. Repeat the process for the other events associated with the incident.

Root cause analysis does not mean the investigation is over. Look at technique, or other systems outside the normal indicators. Often creative thinking will find root causes that ordinarily would be missed, and continue to plague the laboratory or operation.

12.3.4 Monitoring of the Corrective Actions

- The Technical Manager and QA Manager are responsible to ensure that the corrective action taken was effective.
- Ineffective actions are documented and re-evaluated until acceptable resolution is achieved. Technical Managers are accountable to the Laboratory Director to ensure final acceptable resolution is achieved and documented appropriately.
- The QA Manager reviews monthly NCMs and ICAT records for trends. Highlights are included in the QA monthly report (refer to Section 16). If a significant trend develops that adversely affects quality, an audit of the area is performed and corrective action implemented.
- Any out-of-control situations that are not addressed acceptably at the laboratory level may be reported to the Corporate Quality Director by the QA Manager, indicating the nature of the out-of-control situation and problems encountered in solving the situation.

12.3.5 Follow-up Audits

- Follow-up audits may be initiated by the QA Manager and shall be performed as soon as possible when the identification of a nonconformance casts doubt on the laboratory's compliance with its own policies and procedures, or on its compliance with state or federal requirements.
- These audits often follow the implementation of the corrective actions to verify effectiveness. An additional audit would only be necessary when a critical issue or risk to business is discovered.

(Also refer to Section 15.1.4, Special Audits.)

12.4 Technical Corrective Actions

In addition to providing acceptance criteria and specific protocols for technical corrective actions in the method SOPs, the laboratory has general procedures to be followed to determine when departures from the documented policies and procedures and quality control have occurred (refer to Section 11). The documentation of these procedures is through the use of an NCM or record in the ICAT system.

Table 12-1 includes examples of general technical corrective actions. For specific criteria and corrective actions, refer to the analytical methods or specific method SOPs. The laboratory may also maintain Work Instructions on these items that are available upon request.

Table 12-1 provides some general guidelines for identifying the individual(s) responsible for assessing each QC type and initiating corrective action. The table also provides general guidance on how a data set should be treated if associated QC measurements are unacceptable. Specific procedures are included in Method SOPs, Work Instructions, QAM Sections 19 and 20. All corrective actions are reviewed monthly, at a minimum, by the QA Manager and highlights are included in the QA monthly report.

To the extent possible, samples shall be reported only if all quality control measures are acceptable. If the deficiency does not impair the usability of the results, data will be reported with an appropriate data qualifier and/or the deficiency will be noted in the case narrative. Where sample results may be impaired, the Project Manager is notified by an NCM and appropriate corrective action (e.g., reanalysis) is taken and documented**.**

12.5 Basic Corrections

When mistakes occur in records, each mistake shall be crossed-out, [not obliterated (e.g. no white-out)], and the correct value entered alongside. All such corrections shall be initialed (or signed) and dated by the person making the correction. In the case of records stored electronically, the original uncorrected file must be maintained intact and a second corrected file is created.

This same process applies to adding additional information to a record. All additions made later than the initial must also be initialed (or signed) and dated.

When corrections are due to reasons other than obvious transcription errors, the reason for the corrections (or additions) shall also be documented.

Table 12-1

Example – General Corrective Action Procedures

QC Activity *(Individual Responsible for Initiation/Assessment)*	Acceptance Criteria	Recommended Corrective Action
Initial Instrument Blank *(Analyst)*	- Instrument response < MDL	- Prepare another blank. - If same response, determine cause of contamination: reagents, environment, instrument equipment failure, etc..
Initial Calibration Standards *(Analyst, Technical Manager(s))*	- Correlation coefficient > 0.99 or 0.995 or: standard concentration value - Read-back errors within acceptance range - % Recovery within acceptance range - See details in Method SOP	- Reanalyze standards. - If still unacceptable, remake standards and recalibrate instrument.
Independent Calibration Verification (Second Source) *(Analyst, Technical Manager(s))*	- % Recovery within control limits	- Remake and reanalyze standard. - If still unacceptable, then remake calibration standards or use new primary standards and recalibrate instrument.
Continuing Calibration Standards *(Analyst, Data Reviewer)*	% Recovery within control limits	- Reanalyze standard. - If still unacceptable, then recalibrate and rerun affected samples.
Matrix Spike / Matrix Spike Duplicate (MS/MSD) *(Analyst, Data Reviewer)*	- % Recovery within limits documented in LIMS	- If the acceptance criteria for duplicates or matrix spikes are not met because of matrix interferences, the acceptance of the analytical batch is determined by the validity of the LCS. - If the LCS is within acceptable limits the batch is acceptable. - The results of the duplicates, matrix spikes and the LCS are reported with the data set. - For matrix spike or duplicate results outside criteria the data for that sample shall be reported with qualifiers.

QC Activity *(Individual Responsible for Initiation/Assessment)*	Acceptance Criteria	Recommended Corrective Action
Laboratory Control Sample (LCS) *(Analyst, Data Reviewer)*	- % Recovery within limits specified in LIMS	- Batch must be re-prepared and re-analyzed. This includes any allowable marginal exceedance. When not using marginal exceedances, the following exceptions apply: 1) when the acceptance criteria for the positive control are exceeded high (i.e., high bias) and there are associated samples that are non-detects, then those non-detects may be reported with data qualifying codes; 2) when the acceptance criteria for the positive control are exceeded low (i.e., low bias), those sample results may be reported if they exceed a maximum regulatory limit/decision level with data qualifying codes. **Note:** If there is insufficient sample or the holding time cannot be met, contact client and report with flags.
Surrogates *(Analyst, Data Reviewer)*	- % Recovery within limits of method or within three standard deviations of the historical mean	- Individual sample must be repeated. Place comment in TALS. - Surrogate results outside criteria shall be reported with qualifiers.
Method Blank (MB) *(Analyst, Data Reviewer)*	< Reporting Limit [1] For common lab contaminants, no analytes detected at greater than and equal to RL.	- Reanalyze blank. - If still positive, determine source of contamination. If necessary, reprocess (i.e. digest or extract) entire sample batch. Report blank results. - Qualify the result(s) if the concentration of a targeted analyte in the MB is at or above the reporting limit and is > 1/10 of the amount measured in the sample.
Proficiency Testing (PT) Samples *(QA Manager, Technical Manager(s))*	- Criteria supplied by PT Supplier	- Any failures or warnings must be investigated for cause. Failures may result in the need to repeat a PT sample to show the problem is corrected.
Internal / External Audits *(QA Manager, Technical Manager(s), Laboratory Director)*	- Defined in Quality System documentation such as SOPs, QAM, etc.	- Non-conformances must be investigated through ICAT system and necessary corrections must be made.
Reporting / Calculation Errors (Depends on issue – possible individuals include: Analysts, Data Reviewers, Project Managers, *Technical Manager(s)*, QA Manager, Corporate QA, Corporate Management)	- Corporate SOP CW-Q-S-005, Data Recall	- Corrective action is determined by type of error. Follow the procedures in Corporate SOP CW-L-S-002, Internal Investigations, or laboratory SOP PT-QA-016.

QC Activity *(Individual Responsible for Initiation/Assessment)*	Acceptance Criteria	Recommended Corrective Action
Client Complaints *(Project Managers, Lab Director, Sales and Marketing)*	-	- Corrective action is determined by the type of complaint. For example, a complaint regarding an incorrect address on a report will result in the report being corrected and then follow-up must be performed on the reasons the address was incorrect (e.g., database needs to be updated).
QA Monthly Report (Refer to Section 16 for an example) (QA Manager, Lab Director, *Technical Manager(s)*)	- QAM, SOPs	- Corrective action is determined by the type of issue. For example, NCMs and ICAT records for the month are reviewed and possible trends are investigated.
Health and Safety Violation (Safety Officer, Lab Director, *Technical Manager(s)*)	- Environmental Health and Safety (EHS) Manual	- Non-conformance is investigated and corrected through ICAT system.

Note:

1. Except as noted below for certain compounds, the method blank should be below the reporting limit unless there is a client specific requirement or method requirement to be evaluated to a lower level. Concentrations up to five times the reporting limit will be allowed for the ubiquitous laboratory and reagent contaminants: methylene chloride, toluene, acetone, 2-butanone and phthalates provided that they appear in similar levels in the reagent blank and samples. This allowance presumes that the detection limit is significantly below any regulatory limit to which the data are to be compared and that blank subtraction will not occur. For benzene and ethylene dibromide (EDB) and other analytes for which regulatory limits are extremely close to the detection limit, the method blank must be below the method detection limit.

SECTION 13

PREVENTIVE ACTION / IMPROVEMENT

13.1 Overview

The laboratory's preventive action programs improve or eliminate potential causes of nonconforming product and/or nonconformance to the quality system. This preventive action process is a proactive and continuous process if improvement activities that can be initiated through feedback from clients, employees, business providers, and affiliates. The QA Department has the overall responsibility to ensure that the preventive action process is in place, and that relevant information on actions is submitted for management review.

Dedicating resources to an effective preventive action system emphasizes the laboratory's commitment to its Quality Program. It is beneficial to identify and address negative trends before they develop into complaints, problems and corrective actions. Additionally, the laboratory continually strives to improve customer service and client satisfaction through continuous improvements to laboratory systems.

Opportunities for improvement may be discovered through any of the following on the Preventative Action Schedule:

Preventative Action	Frequency
Management System Review	Annually
Review of QA Metrics	Monthly
Trending NCMs	Monthly
Review of Control Charts of QC Results	At least annually
Trending PT Results	Semi-annually
Trending Client Complaints	Monthly
Review of Revised Reports and Invoices	Monthly
Review of Process Operations	At least annually
Staff Observations and Suggestions	As they arise

The monthly Management Systems Metrics Report shows performance indicators in all areas of the laboratory and quality system. These areas include revised reports, corrective actions, audit findings, internal auditing and data authenticity audits, client complaints, PT samples, holding time violations, SOPs, ethics training, etc. The metrics report is reviewed monthly by laboratory management, Corporate QA and Eurofins TestAmerica's Executive Committee. These metrics are used in evaluating the management and quality system performance on an ongoing basis and provide a tool for identifying areas for improvement.

Items identified as continuous improvement opportunities to the management system may be issued as goals from the annual management systems review, recommendations from internal audits, white papers, Lesson Learned, Technical Services audit report, Technical Best Practices, or as Corporate or management initiatives.

The laboratory's corrective action process is integral to implementation of preventive actions. A critical piece of the corrective action process is the implementation of actions to prevent further occurrence of a non-compliance event. Historical review of corrective action and non-conformances provides a valuable mechanism for identifying preventive action opportunities.

13.1.1 The following elements are part of a preventive action/process improvement system:

- Identification of an opportunity for preventive action or process improvement
- Process for the preventive action or improvement
- Define the measurements of the effectiveness of the process once undertake
- Execution of the preventive action or improvement
- Evaluation of the plan using the defined measurements
- Verification of the effectiveness of the preventive action or improvement
- Close-Out by documenting any permanent changes to the Quality System as a result of the Preventive Action or Process Improvement. Documentation of Preventive Action/ Process Improvement is incorporated into the monthly QA reports, corrective action process and management review.

13.1.2 Any Preventive Actions/ Process Improvements undertaken or attempted shall be taken into account during the Annual Management Systems Review (Section 16). A highly detailed report is not required; however a summary of success and failure within the preventive action program is sufficient to provide management with a measurement for evaluation.

13.2 Management Of Change

The Management of Change process is designed to manage significant events and changes that occur within the laboratory. Through these procedures, the potential risks inherent with a new event or change are identified and evaluated. The risks are minimized or eliminated through pre-planning and the development of preventive measures. The types of indicators monitored under this collective system include:

Change Type	Examples
Facility Changes	-movement of prep or instrument groups to a new location in the laboratory -introduction of significant changes in air handling or gas and solvent delivery systems -significant room additions or renovations -significant electrical or network upgrades or changes
Major Accreditation Changes	-voluntary surrender of accreditations no longer deemed necessary to the laboratory -loss of accreditation -addition of new accreditation programs
Reagents and Waste Streams	- new chemicals/reagents not previously used in the laboratory -deletion of chemicals/reagents that will mean they are no longer used at all in the laboratory -major changes to the volume of chemicals/reagents being used - a new waste stream must be developed Note: See EHS for changes in waste streams
Addition or Deletion of Laboratory Capabilities	-implementation of new regulated methods -“retiring” of active methods -method development for “in-house” methods Note: New regulatory methods and method development require specific processes and documentation before the process can begin or the method can enter production. See QA and EHS for requirements.
LIMS changes	-large system upgrades -additions of new capabilities Note: These changes are handled on a Corporate level
Key Personnel Changes	-key personnel promotions and their effect on that individuals group (experience, productivity, leadership, manpower) -key personnel losses -impact of new personnel that may add new experience or capabilities to the laboratory
New Types of	-addition of a new instrument class/technology

Instrumentation	-significant instrument upgrades that impact sensitivity, productivity or capability Note: New instrumentation requires collection and submission of instrument IDOC information before entering production. See QA for requirements.
Changes in Quality Systems and Policies	-implementation of a new Corrective Action System -changes to the Internal Audit program -implementation of uploads for Proficiency Testing samples

SECTION 14

CONTROL OF RECORDS

The laboratory maintains a records management system appropriate to its needs and that complies with applicable standards or regulations as required. The system produces unequivocal, accurate records that document all laboratory activities. The laboratory retains all original observations, calculations and derived data, calibration records and a copy of the analytical report for a minimum of five years after it has been issued. Exceptions for programs with longer retention requirements are discussed in section 14.1.2.

14.1 Overview

The laboratory has established procedures for identification, collection, indexing, access, filing, storage, maintenance and disposal of quality and technical records. A record index is listed in Table 14-1. More detailed information on retention of specific records is provided in Corporate Policy No.CW-L-P-001, *Records Retention Policy*, and Work Instruction No. CW-L-WI-001, *Eurofins TestAmerica Records Retention/Storage Schedule*. Quality records are maintained by the Quality Assurance (QA) department electronically on the corporate designated QA network drive which is backed up as part of the regular network backup. Records are of two types; either electronic or hard copy paper formats, depending on whether the record is computer or hand generated (some records may be in both formats). Technical records are maintained by the CSO group, HR, and the QA department and as outlined in laboratory SOP PT-QA-019.

Table 14-1 Record Index[1]

	Record Types [1]:	Retention Time:
Technical Records	- Raw Data - Logbooks[2] - Standards - Certificates - Analytical Records - MDLs/IDLs/DOCs - Lab Reports	5 Years from analytical report issue*
Official Documents	- Quality Assurance Manual (QAM) - Work Instructions - Policies - SOPs - Policy Memorandums - Manuals - Published Methods	Indefinitely
QA Records	- Certifications - Method and Software Validation / Verification Data	Indefinitely

	Record Types [1]:	Retention Time:
QA Records	- Internal & External Audits/Responses - Corrective/Preventive Actions - Management Reviews - Data Investigation	5 Years from archival* **Data Investigation:** 5 years or the life of the affected raw data storage whichever is greater (beyond 5 years if ongoing project or pending investigation)
Project Records	- Sample Receipt & COC Documents - Contracts and Amendments - Correspondence - QAPP - SAP - Telephone Logbooks - Lab Reports	5 Years from analytical report issue*
Administrative Records	Financial and Business Operations	Refer to CW-L-WI-001
	EH&S Manual, Permits	Indefinitely
	Disposal Records	Indefinitely
	Employee Handbook	Indefinitely
	Personnel files, Employee Signature & Initials, Administrative Training Records (e.g., Ethics)	Refer to HR Manual
	Administrative Policies	Indefinitely
	Technical Training Records	7 years
	Legal Records	Indefinitely
	HR Records	Refer to CW-L-WI-001
	IT Records	Refer to CW-L-WI-001
	Corporate Governance Records	Refer to CW-L-WI-001
	Sales & Marketing	5 years
	Real Estate	Indefinitely

[1] Record Types encompass hardcopy and electronic records.
[2] Examples of Logbook types: Maintenance, Instrument Run, Preparation (standard and samples), Standard and Reagent Receipt, Archiving, Balance Calibration, Temperature (hardcopy or electronic records).
* Exceptions listed in Table 14-2.

14.1.1 All records are stored and retained in such a way that they are secure and readily retrievable at the laboratory facility or an offsite location that provides a suitable environment to prevent damage or deterioration and to prevent loss at the laboratory or the Iron Mountain data storage facility. All records shall be protected against fire, theft, loss, environmental deterioration, and vermin. In the case of electronic records, electronic or magnetic sources, storage media are protected from deterioration caused by magnetic fields and/or electronic deterioration.

Access to the data is limited to laboratory and company employees and shall be documented with an access log**.** Records archived off-site are stored in a secure location where a record is maintained of any entry into the storage facility. Whether on-site or off-site storage is used, logs are maintained in each storage box to note removal and return of records. Retention of records are maintained on-site at the laboratory for at least 1 year after their generation and moved offsite for the remainder of the required storage time. Records are maintained for a minimum of five years unless otherwise specified by a client or regulatory requirement.

For raw data and project records, record retention shall be calculated from the date the project report is issued. For other records, such as Controlled Documents, QA, or Administrative Records, the retention time is calculated from the date the record is formally retired. Records related to the programs listed in Table 14-2 have lengthier retention requirements and are subject to the requirements in Section 14.1.3.

14.1.2 Programs with Longer Retention Requirements

Some regulatory programs have longer record retention requirements than the standard record retention time. These are detailed in Table 14-2 with their retention requirements. In these cases, the longer retention requirement is enacted. If special instructions exist such that client data cannot be destroyed prior to notification of the client, the container or box containing that data is marked as to who to contact for authorization prior to destroying the data.

Table 14-2 Special Record Retention Requirements

Program	[1]Retention Requirement
Drinking Water – All States	10 years (lab reports and raw data)
Commonwealth of MA – All environmental data 310 CMR 42.14	10 years
FIFRA – 40 CFR Part 160	Retain for life of research or marketing permit for pesticides regulated by EPA
Housing and Urban Development (HUD) Environmental Lead Testing	10 years
Alaska	10 years
Louisiana – All	10 years
Michigan Department of Environmental Quality – all environmental data	10 years
Ohio VAP	10 years and State contact prior to disposal
OSHA	30 years

[1]Note: Extended retention requirements must be noted with the archive documents or addressed in facility-specific records retention procedures.

14.1.3 The laboratory has procedures to protect and back-up records stored electronically and to prevent unauthorized access to or amendment of these records. All analytical data is maintained as hard copy or in a secure readable electronic format. For analytical reports that are maintained as copies in PDF format, refer to Section 19.15.1 and laboratory SOP PT-QA-019, Records Management, Retention, and Archive, for more information.

14.1.4 The record keeping system allows for historical reconstruction of all laboratory activities that produced the analytical data, as well as rapid recovery of historical data (Records stored off site should be accessible within 2 days of a request for such records). The history of the sample from when the laboratory took possession of the samples must be readily understood through the documentation. This shall include inter-laboratory transfers of samples and/or extracts.

- The records include the identity of personnel involved in sampling, sample receipt, preparation, or testing. All analytical work contains the initials (at least) of the personnel

involved. The laboratory's copy of the chain of custody is stored with the invoice and the work order sheets generated by TALS. Details of the COC linking procedure are described in SOP PT-SR-001. The chain of custody would indicate the name of the sampler. Any sampling notes provided with the chain of custody are also scanned into TALS.

- All information relating to the laboratory facilities equipment, analytical test methods, and related laboratory activities, such as sample receipt, sample preparation, or data verification are documented.
- The record keeping system facilitates the retrieval of all working files and archived records for inspection and verification purposes (e.g., set format for naming electronic files, set format for what is included with a given analytical data set are described in SOP PT-QA-019. Instrument data is stored sequentially by instrument. Run logs are maintained for each instrument; a copy of each day's run long is stored in the electronic files along with the data to aid in re-constructing an analytical sequence. Where an analysis is performed without an instrument, bound logbooks or bench sheets are used to record and file data or the data is entered directly into TALS as the analysis is done. Standard and reagent information is recorded in electronic standard log in TALS, and is associated with each preparation and analytical batch for which they are used.
- Changes to hardcopy records shall follow the procedures outlined in Section 12 and 19. Changes to electronic records in TALS or instrument data are recorded in audit trails.
- The reason for a signature or initials on a document is clearly indicated in the records such as "sampled by," "prepared by," "reviewed by", or "analyzed by".
- All generated data, except those that are generated by automated data collection systems, are recorded directly, promptly and legibly in permanent dark ink.
- Hard copy data may be scanned into PDF format for record storage as long as the scanning process can be verified in order to ensure that no data is lost and the data files and storage media must be tested to verify the laboratory's ability to retrieve the information prior to the destruction of the hard copy that was scanned. The procedure for this verification can be found in SOP PT-QA-019.
- Also refer to Section 19.15.1 'Computer and Electronic Data Related Requirements'**.**

14.2 Technical And Analytical Records

14.2.1 The laboratory retains records of original observations, derived data and sufficient information to establish an audit trail, calibration records, staff records and a copy of each analytical report issued, for a minimum of five years unless otherwise specified by a client or regulatory requirement. The records for each analysis shall contain sufficient information to enable the analysis to be repeated under conditions as close as possible to the original. The records shall include the identity of laboratory personnel responsible for the sampling, performance of each analysis and reviewing results.

14.2.2 Observations, data and calculations are recorded real-time and are identifiable to the specific task.

14.2.3 Changes to hardcopy records shall follow the procedures outlined in Section 12 and 19. Changes to electronic records in TALS or instrument data are recorded in audit trails.

The essential information to be associated with analysis, such as strip charts, tabular printouts, computer data files, analytical notebooks, and run logs, include:

- Laboratory sample ID code**;**
- Date of analysis; Time of Analysis is also required if the holding time is seventy-two (72) hours or less, or when time critical steps are included in the analysis (e.g., drying times, incubations, etc.); instrumental analyses have the date and time of analysis recorded as part of their general operations. Where a time critical step exists in an analysis, location for such a time is included as part of the documentation in a specific logbook, on a benchsheet or in TALS.
- Instrumentation identification and instrument operating conditions/parameters. Operating conditions/parameters are typically recorded in method specific SOPs or in instrument maintenance logs where available.
- analysis type**;**
- all manual calculations and manual integrations**;**
- analyst's or operator's initials/signature**;**
- sample preparation including cleanup, separation protocols, incubation periods or subculture, ID codes, volumes, weights, instrument printouts, meter readings, calculations, reagents**;**
- test results**;**
- standard and reagent origin, receipt, preparation, and use**;**
- calibration criteria, frequency and acceptance criteria**;**
- data and statistical calculations, review, confirmation, interpretation, assessment and reporting conventions**;**
- quality control protocols and assessment**;**
- electronic data security, software documentation and verification, software and hardware audits, backups, and records of any changes to automated data entries; and
- Method performance criteria including expected quality control requirements. These are indicated both in the TALS and on specific analytical report formats**.**

14.2.4 All logbooks used during receipt, preparation, storage, analysis, and reporting of samples or monitoring of support equipment shall undergo a periodic, documented supervisory or peer review.

14.3 Laboratory Support Activities

In addition to documenting all the above-mentioned activities, the following are retained QA records and project records (previous discussions in this section relate where and how these data are stored):

- all original raw data, whether hard copy or electronic, for calibrations, samples and quality control measures, including analysts' work sheets and data output records (chromatograms, strip charts, and other instrument response readout records)**;**
- a written description or reference to the specific test method used which includes a description of the specific computational steps used to translate parametric observations into a reportable analytical value**;**
- copies of final reports**;**
- archived SOPs**;**
- correspondence relating to laboratory activities for a specific project**;**
- all corrective action reports, audits and audit responses**;**
- proficiency test results and raw data; and
- results of data review, verification, and crosschecking procedures

14.3.1 Sample Handling Records

Records of all procedures to which a sample is subjected while in the possession of the laboratory are maintained. These include but are not limited to records pertaining to:

- sample preservation including appropriateness of sample container and compliance with holding time requirement;
- sample identification, receipt, acceptance or rejection and login;
- sample storage and tracking including shipping receipts, sample transmittal / COC forms; and
- procedures for the receipt and retention of samples, including all provisions necessary to protect the integrity of samples.

14.4 Administrative Records

The laboratory also maintains the administrative records in either electronic or hard copy form. Refer to Table 14-1.

14.5 Records Management, Storage And Disposal

All records (including those pertaining to test equipment), certificates and reports are safely stored, held secure and in confidence to the client. Certification related records are available upon request.

All information necessary for the historical reconstruction of data is maintained by the laboratory. Records that are stored only on electronic media must be supported by the hardware and software necessary for their retrieval.

Records that are stored or generated by computers or personal computers have hard copy, write-protected backup copies, or an electronic audit trail controlling access**.**

The laboratory has a record management system (a.k.a., document control) for control of laboratory notebooks/benchsheets, instrument/equipment logbooks, and records for data reduction, validation and reporting. Laboratory notebooks are issued on a per analysis basis, as needed, and are numbered sequentially. All sample data are recorded in TALS. Bench sheets are filed sequentially. Standards are maintained in the electronic standards in TALS**.** Records are considered archived when noted as such in the records management system (a.k.a., document control).

14.5.1 Transfer of Ownership

In the event that the laboratory transfers ownership or goes out of business, the laboratory shall ensure that the records are maintained or transferred according to client's instructions. Upon ownership transfer, record retention requirements shall be addressed in the ownership transfer agreement and the responsibility for maintaining archives is clearly established. In addition, in cases of bankruptcy, appropriate regulatory and state legal requirements concerning laboratory records must be followed. In the event of the closure of the laboratory, all records will revert to the control of the Corporate headquarters. Should the entire company cease to exist, as much notice as possible will be given to clients and the accrediting bodies who have worked with the laboratory during the previous 5 years of such action.

14.5.2 Records Disposal

Records are removed from the archive and destroyed after 5 years, unless otherwise specified by a client or regulatory requirement. On a project specific or program basis, clients may need to be notified prior to record destruction. Records are destroyed in a manner that ensures their confidentiality such as shredding, mutilation or incineration. (Refer to Tables 14-1 and 14-2).

Electronic copies of records must be destroyed by erasure or physically damaging off-line storage media so no records can be read.

If a third party records management company is hired to dispose of records, a "Certificate of Destruction" is required.

SECTION 15

AUDITS

15.1 Internal Audits

Internal audits are performed to verify that laboratory operations comply with the requirements of the lab's quality system and with the external quality programs under which the laboratory operates. Audits are planned and organized by the QA staff. Personnel conducting the audits should be independent of the area being evaluated. Auditors will have sufficient authority, access to work areas, and organizational freedom necessary to observe all activities affecting quality and to report the assessments to laboratory management and when requested to Corporate management.

Audits are conducted and documented as described in the Corporate SOP No. CW-Q-S-003, *Internal Auditing*. More detail on the specific elements for internal audits and data audit is described in Pittsburgh Laboratory SOP No. PT-QA-002, *Internal Auditing*. The types and frequency of routine internal audits are shown in Table 15-1. Special or ad hoc assessments may be conducted as needed under the direction of the QA staff.

Table 15-1 Types of Internal Audits and Frequency

Description	Performed by	Frequency
Quality Systems Audits	QA Department, QA approved designee, or Corporate QA	All areas of the laboratory annually
Method Audits QA Technical Data Audits*	Joint responsibility: a) QA Manager or designee b) Technical Manager or Designee (Refer to CW-Q-S-003)	50% of methods annually

Description	Performed by	Frequency
SOP Method Compliance*	Joint responsibility: c) QA Manager or designee d) Technical Manager or Designee (Refer to CW-Q-S-003)	Every 2 years
Special	QA Department or Designee	Surveillance or spot checks performed as needed, e.g., to confirm corrective actions from other audits.
Performance Testing	Analysts with QA oversight	Two successful per year for each TNI field of testing or as dictated by regulatory requirements

*Technical Data and Method Compliance audits are in addition to the annual Quality Systems Audit

15.1.1 Annual Quality Systems Audit

An annual quality systems audit is required to ensure compliance to analytical methods and SOPs, Eurofins TestAmerica's Data Integrity and Ethics Policies, TNI quality systems, client and state requirements, and the effectiveness of the internal controls of the analytical process, including, but not limited to, data review, quality controls, preventive action and corrective action. The completeness of earlier corrective actions is assessed for effectiveness & sustainability. The audit is divided into sections for each operating or support area of the lab, and each section is comprehensive for a given area. The area audits may be performed on a rotating schedule throughout the year to ensure adequate coverage of all areas. This schedule may change as situations in the laboratory warrant. See SOP PT-QA-002 for auditing area details.

Effectiveness of training will be determined during our annual QA systems evaluation. Evidence of successful training includes:

- Audit and surveillance results, control charts, proficiency testing results, data analysis, corrective and preventive actions, customer feedback, and management reviews in efforts to monitor trends and continually improve the quality system:
- Adequate documentation of training within operational areas, including one-on-one technical training for individual technologies, and for people cross-trained.
- Analysts knowledge of QA Manual and SOPs. Analysts following SOPs, i.e., practice matches SOPs.
- Analysts regularly communicate to supervisors and QA if SOPs need revision.

15.1.2 QA Technical Data Audits

QA technical audits assess data authenticity and analyst integrity. These audits are based on client projects, associated sample delivery groups, and the methods performed. Reported results are compared to raw data to verify the authenticity of results. The validity of calibrations and QC results are compared to data qualifiers, footnotes, and case narratives. Documentation is assessed by examining run logs and records of manual integrations. Manual calculations are checked. Where possible, electronic audit miner programs (e.g., Chrom AuditMiner) are used to identify unusual manipulations of the data deserving closer scrutiny. QA technical audits will include all methods within a two-year period. All analysts and data reviewers should be reviewed over the course of a two year period through at least one QA Technical Audit.

15.1.3 SOP Method Compliance

Compliance of all SOPs with the source methods and compliance of the operational groups with the SOPs will be assessed by the QA department, Technical Manager, or qualified designee at least every two years. It is also recommended that the work of each newly hired analyst is assessed within 3 months of working independently, (e.g., completion of method IDOC). In addition, as analysts add methods to their capabilities, reviews (new IDOC) of the analyst work products will be performed within 3 months of completing the documented training.

15.1.4 Special Audits

Special audits are conducted on an as needed basis, generally as a follow up to specific issues such as client complaints, corrective actions, PT results, data audits, system audits, validation comments, regulatory audits or suspected ethical improprieties. Special audits are focused on a specific issue, and report format, distribution, and timeframes are designed to address the nature of the issue.

15.1.5 Performance Testing

The laboratory participates semi-annually in performance audits conducted through the analysis of PT samples provided by a third party. The laboratory generally participates in the following types of PT studies: Water Pollution Program, Water Supply Program, Hazardous Waste Program, client supplied PTs and Lab internal PTs.

It is Eurofins TestAmerica's policy that PT samples be treated as typical samples in the production process. Furthermore, where PT samples present special or unique problems, in the regular production process they may need to be treated differently, as would any special or unique request submitted by any client. The QA Manager must be consulted and in agreement with any decisions made to treat a PT sample differently due to some special circumstance.

Unacceptable PT results are required to be entered into the ICAT system for investigation. In some cases it may be necessary for blind QC samples to be submitted to the laboratory to show a return to control.

15.2 EXTERNAL AUDITS

External audits are performed when certifying agencies or clients conduct on-site inspections or submit performance testing samples for analysis. It is Eurofins TestAmerica's policy to cooperate fully with regulatory authorities and clients. The laboratory makes every effort to provide the auditors with access to personnel, documentation, and assistance. Laboratory supervisors are responsible for providing corrective actions to the QA Manager who coordinates the response. Audit responses are due in the time allotted by the client or agency performing the audit. When requested, a copy of the audit report and the labs corrective action plan will be forwarded to Corporate Quality.

The laboratory cooperates with clients and their representatives to monitor the laboratory's performance in relation to work performed for the client. The client may only view data and systems related directly to the client's work. All efforts are made to keep other client information confidential.

15.2.1 Confidential Business Information (CBI) Considerations

During on-site audits, auditors may come into possession of information claimed as business

confidential. A business confidentiality claim is defined as "a claim or allegation that business information is entitled to confidential treatment for reasons of business confidentiality or a request for a determination that such information is entitled to such treatment." When information is claimed as business confidential, the laboratory must place on (or attach to) the information at the time it is submitted to the auditor, a cover sheet, stamped or typed legend or other suitable form of notice, employing language such as "trade secret", "proprietary" or "company confidential". Confidential portions of documents otherwise non-confidential must be clearly identified. CBI may be purged of references to client identity by the responsible laboratory official at the time of removal from the laboratory. However, sample identifiers may not be obscured from the information. Additional information regarding CBI can be found in within the 2009 TNI standards.

15.3 Audit Findings

Audit findings are documented using the ICAT system (see Section 12). The laboratory's corrective action responses may include action plans that could not be completed within a predefined timeframe. In these instances, a completion date must be set and agreed to by operations management and the QA Manager.

Developing and implementing corrective actions to findings is the responsibility of the Technical Manager where the finding originated. Findings that are not corrected by specified due dates are reported monthly to management in the QA monthly report. When requested a copy of the audit report and the labs corrective action plan will be forwarded to Corporate Quality.

If any audit finding casts doubt on the effectiveness of the operations or on the correctness or validity of the laboratory's test results, the laboratory shall take timely corrective action, and shall notify clients in writing if the investigations show that the laboratory results have been affected. Once corrective action is implemented, a follow-up audit is scheduled to ensure that the problem has been corrected.

Clients must be notified promptly, in writing, of any event such as the identification of defective measuring or test equipment that casts doubt on the validity of results given in any test report or amendment to a test report. The investigation must begin within 24-hours of discovery of the problem and all efforts are made to notify the client within two weeks after completion of the investigation.

SECTION 16
MANAGEMENT REVIEWS

16.1 Quality Assurance Report

A comprehensive QA Report shall be prepared each month by the laboratory's QA Department and forwarded to the Laboratory Director, Technical Managers, their Quality Director as well as the VP of Operations. All aspects of the QA system are reviewed to evaluate the suitability of policies and procedures. During the course of the year, the Laboratory Director, VP of Operations, or Corporate QA may request that additional information be added to the report.

On a monthly basis, Corporate QA compiles information from all the monthly laboratory reports. The Corporate Quality Directors prepare a report that includes a compilation of all metrics and notable information and concerns regarding the QA programs within the laboratories. The report

also includes a listing of new regulations that may potentially impact the laboratories. This report is presented to the Senior Management Team and VPs of Operations.

16.2 Annual Management Review

The senior lab management team (Laboratory Director, QA Manager, and Technical Managers) conducts a review annually of its quality systems and TALS to ensure its continuing suitability and effectiveness in meeting client and regulatory requirements and to introduce any necessary changes or improvements. It will also provide a platform for defining goals & objectives and action items that feed into the laboratory planning system. Corporate Operations and Corporate QA personnel is to be included in this meeting at the discretion of the Laboratory Director. The TALS review consists of examining any audits, complaints or concerns that have been raised through the year that are related to the TALS. The laboratory will summarize any critical findings that cannot be solved by the lab and report them to Corporate IT.

The Management System Review (see Corporate SOP No. CW-Q-S-004, *Management System Review*, and Work Instruction No. CW-Q-WI-003) uses information generated during the preceding year to assess the "big picture" by ensuring that routine actions taken and reviewed on a monthly basis are not components of larger systematic concerns. The monthly review should keep the quality systems current and effective, therefore, the annual review is a formal senior management process to review specific existing documentation. Significant issues from the following documentation are compiled or summarized by the QA Manager prior to the review meeting:

- Matters arising from the previous annual review
- Prior Monthly QA Reports issues
- Laboratory QA Metrics
- Review of report reissue requests
- Review of client feedback and complaints
- Issues arising from any prior management or staff meetings
- Minutes from prior senior lab management meetings - Issues that may be raised from these meetings include:
    - Adequacy of staff, equipment and facility resources.
    - Adequacy of policies and procedures.
    - Future plans for resources and testing capability and capacity.
- The annual internal double blind PT program sample performance
- Compliance to the Ethics Policy and Data Integrity Plan, including any evidence/incidents of inappropriate actions or vulnerabilities related to data Integrity
- Review of Corrective and Preventative Actions, assessments by external bodies and recommendations for improvement
- Evaluation of overall risk, including risks to impartiality, confidentiality, reporting statements of conformity, and nonconforming work.

A report is generated by the QA Manager and management. The report is distributed to the appropriate VP of Operation and the Quality Director. The report includes, but is not limited to:

- The date of the review and the names and titles of participants
- A reference to the existing data quality related documents and topics that were reviewed

- Quality system or operational changes or improvements that will be made as a result of the review [e.g., an implementation schedule including assigned responsibilities for the changes (Action Table)]

Changes to the quality systems requiring update to the laboratory QA Manual shall be included in the next revision of the QA Manual.

16.3 Potential Integrity Related Managerial Reviews

Potential integrity issues (data or business related) must be handled and reviewed in a confidential manner until such time as a follow-up evaluation, full investigation, or other appropriate actions have been completed and issues clarified. Eurofins TestAmerica's Corporate Internal Investigation and Data Recall SOPs shall be followed (SOP No. CW-L-S-002 and CW-Q-S-005). All investigations that result in finding of inappropriate activity are documented and include any disciplinary actions involved, corrective actions taken, and all appropriate notifications of clients.

Eurofins TestAmerica's President and CEO, Executive VP of Operations, VP of Client & Technical Services, VPs of Operation, and Quality Directors receive a monthly report from the VP-QA/EHS summarizing any current data integrity or data recall investigations. The VP's of Operation are also made aware of progress on these issues for their specific labs.

SECTION 17

PERSONNEL

17.1 Overview

The laboratory's management believes that its highly qualified and professional staff is the single most important aspect in assuring a high level of data quality and service. The staff consists of professionals and support personnel as outlined in the organization chart in Figure 4-1.

All personnel must demonstrate competence in the areas where they have responsibility. Any staff that is undergoing training shall have appropriate supervision until they have demonstrated their ability to perform their job function on their own. Staff shall be qualified for their tasks based on appropriate education, training, experience and/or demonstrated skills as required.

The laboratory employs sufficient personnel with the necessary education, training, technical knowledge and experience for their assigned responsibilities.

All personnel are responsible for complying with all QA/QC requirements that pertain to the laboratory and their area of responsibility. Each staff member must have a combination of experience and education to adequately demonstrate a specific knowledge of their particular area of responsibility. Technical staff must also have a general knowledge of lab operations, test methods, QA/QC procedures and records management.

Laboratory management is responsible for formulating goals for lab staff with respect to education, training and skills and ensuring that the laboratory has a policy and procedures for

identifying training needs and providing training of personnel. The training shall be relevant to the present and anticipated responsibilities of the lab staff.

The laboratory only uses personnel that are employed by or under contract to, the laboratory. Contracted personnel, when used, must meet competency standards of the laboratory and work in accordance to the laboratory's quality system.

17.2 Education And Experience Requirements For Technical Personnel

The laboratory makes every effort to hire analytical staffs that possess a college degree (AA, BA, BS) in an applied science with some chemistry in the curriculum. Exceptions can be made based upon the individual's experience and ability to learn. For supervisory positions, the Pennsylvania DEP has education and experience requirements that must be met by the Pittsburgh laboratory personnel, and these are reflected in Table 17-1 below. Selection of qualified candidates for laboratory employment begins with documentation of minimum education, training, and experience prerequisites needed to perform the prescribed task. Minimum education and training requirements for Eurofins TestAmerica employees are outlined in job descriptions and are generally summarized for analytical staff in the table below.

The laboratory maintains job descriptions for all personnel who manage, perform or verify work affecting the quality of the environmental testing the laboratory performs. Job Descriptions are located on the Eurofins TestAmerica intranet site's Human Resources web-page (Also see Section 4 for position descriptions/responsibilities).

Experience and specialized training are occasionally accepted in lieu of a college degree (basic lab skills such as using a balance, pipette or quantitation techniques, etc., are also considered).

Table 17-1 General Requirements for Analytical Staff

Specialty	Education	Experience
Extractions, Digestions, some electrode methods (pH, DO, Redox, etc.), or Titrimetric and Gravimetric Analyses	H.S. Diploma	On the job training (OJT)
GFAA, CVAA, FLAA, Single component or short list Chromatography (e.g., Fuels, BTEX-GC, IC	A college degree in an applied science or 2 years of college and at least 1 year of college chemistry	Or 2 years prior analytical experience is required
ICP, ICPMS, Long List or complex chromatography (e.g., Pesticides, PCB, Herbicides, HPLC, etc.), GCMS	A college degree in an applied science or 2 years of college chemistry	or 5 years of prior analytical experience
Spectra Interpretation	A college degree in an applied science or 2 years of college chemistry	And 2 years relevant experience Or 5 years of prior analytical experience

Specialty	Education	Experience
Technical Manager (s) – **General**	Bachelors Degree in an applied science or engineering with 24 semester hours in chemistry An advanced (MS, PhD.) degree may substitute for one year of experience	And 2 years' experience in environmental analysis of representative analytes for which they will oversee
Technical Manager (s) – **Wet Chem** only (no advanced instrumentation)	Associates degree in an applied science or engineering or 2 years of college with 16 semester hours in chemistry	And 2 years relevant experience
Technical Managers - **Microbiology**	Bachelors degree in applied science with at least 16 semester hours in general microbiology and biology An advanced (MS, PhD.) degree may substitute for one year of experience	And 2 years of relevant experience (1 year if laboratory analysis is limited to coliforms and heterotrophic plate count)
Technical Managers – **Microbiology** limited to analysis of fecal coliforms, total coliforms or heterotrophic bacteria	Associates degree in an applied science or engineering and at least 4 credit hours in biology	And 2 years of relevant experience

When an analyst does not meet these requirements, they can perform a task under the direct supervision of a qualified analyst, peer reviewer or Technical Manager, and are considered an analyst in training. The person supervising an analyst in training is accountable for the quality of the analytical data and must review and approve data and associated corrective actions.

17.3 Training

The laboratory is committed to furthering the professional and technical development of employees at all levels.

Orientation to the laboratory's policies and procedures, in-house method training, and employee attendance at outside training courses and conferences all contribute toward employee proficiency. Below are examples of various areas of required employee training.

Table 17-2 Employee Training Examples

Required Training	Time Frame	Employee Type
Environmental Health & Safety	Prior to lab work	All
Ethics –New Hire Comprehensive	30 days of hire	All
Data Integrity	30 days of hire	Technical and PMs
Quality Assurance	30 days of hire	All
Ethics – Comprehensive Refresher	Annually (within 14 months of previous)	All
Initial Demonstration of Capability (DOC)	Prior to unsupervised method performance	Technical

The laboratory maintains records of relevant authorization/competence, education, professional qualifications, training, skills and experience of technical personnel (including contracted personnel) as well as the date that approval/authorization was given. These records are kept on file at the laboratory. Also refer to "Demonstration of Capability" in Section 19.

The training of technical staff is kept up to date by:

- Each employee must have documentation in their training file that they have read, understood and agreed to follow the most recent version of the laboratory QA Manual and SOPs in their area of responsibility. This documentation is updated as SOPs are updated.
- Documentation from any training courses or workshops on specific equipment, analytical techniques or other relevant topics
- Documentation of proficiency (refer to Section 19).
- An Ethics Agreement signed by each staff member (renewed each year) and evidence of annual ethics training.
- A Confidentiality Agreement signed by each staff member signed at the time of employment.
- Human Resources maintains documentation and attestation forms on employment status & records; benefit programs; timekeeping/payroll; and employee conduct (e.g., ethics violations). This information is maintained in the employee's secured personnel file.

Evidence of successful training could include such items as:

- Adequate documentation of training within operational areas, including one-on-one technical training for individual technologies, and particularly for people cross-trained.
- Analysts knowledge to refer to QA Manual for quality issues.
- Analysts following SOPs, i.e., practice matches SOPs.
- Analysts regularly communicate to supervisors and QA if SOPs need revision, rather than waiting for auditors to find problems.

Further details of the laboratory's training program are described in the Pittsburgh Laboratory SOP No. PT-QA-001, *Employee Orientation and Training*.

17.4 Data Integrity And Ethics Training Program

Establishing and maintaining a high ethical standard is an important element of a Quality System. Ethics and data integrity training is integral to the success of Eurofins TestAmerica and is provided for each employee at Eurofins TestAmerica. It is a formal part of the initial employee comprehensive ethics and data integrity training within 30 days of their start date, and an annual

(within at most 14 months of the previous training) refresher for all employees. Senior management at each facility performs the ethics training for their staff.

In order to ensure that all personnel understand the importance Eurofins TestAmerica places on maintaining high ethical standards at all times; Eurofins TestAmerica has established a Corporate Policy No. CW-L-P-004, *Ethics Policy*, and an Ethics Statement. All initial and annual training is documented by signature on the signed Ethics Statement demonstrating that the employee has participated in the training and understands their obligations related to ethical behavior and data integrity.

Violations of this Ethics Policy will not be tolerated. Employees who violate this policy will be subject to disciplinary actions up to and including termination. Criminal violations may also be referred to the Government for prosecution. In addition, such actions could jeopardize Eurofins TestAmerica's ability to do work on Government contracts, and for that reason, Eurofins TestAmerica has a Zero Tolerance approach to such violations.

Employees are trained as to the legal and environmental repercussions that result from data misrepresentation. Key topics covered in the presentation include:

- Organizational mission and its relationship to the critical need for honesty and full disclosure in all analytical reporting
- Ethics Policy
- How and when to report ethical/data integrity issues and confidential reporting
- Record keeping
- Discussion regarding data integrity procedures
- Specific examples of breaches of ethical behavior (e.g. peak shaving, altering data or computer clocks, improper macros, etc., accepting/offering kickbacks, illegal accounting practices, unfair competition/collusion)
- Internal monitoring, investigations, and data recalls
- Consequences for infractions, including potential for immediate termination, debarment, or criminal prosecution
- Importance of proper written narration / data qualification by the analyst and project manager with respect to those cases where the data may still be usable but are in one sense or another partially deficient

Additionally, a data integrity hotline (1-800-736-9407) is maintained by Eurofins TestAmerica and administered by the Corporate Quality Department.

SECTION 18

ACCOMMODATIONS AND ENVIRONMENTAL CONDITIONS

18.1 Overview

The laboratory is a 33,000 ft^2 secure laboratory facility with controlled access and designed to accommodate an efficient workflow and to provide a safe and comfortable work environment for employees. All visitors sign in and are escorted by laboratory personnel. Access is controlled by various measures.

The laboratory is equipped with structural safety features. Each employee is familiar with the location, use, and capabilities of general and specialized safety features associated with their workplace. The laboratory provides and requires the use of protective equipment including safety glasses, protective clothing, gloves, etc., OSHA and other regulatory agency guidelines regarding required amounts of bench and fume hood space, lighting, ventilation (temperature and humidity controlled), access, and safety equipment are met or exceeded.

Traffic flow through sample preparation and analysis areas is minimized to reduce the likelihood of contamination. Adequate floor space and bench top area is provided to allow unencumbered sample preparation and analysis space. Sufficient space is also provided for storage of reagents and media, glassware, and portable equipment. Ample space is also provided for refrigerated sample storage before analysis and archival storage of samples after analysis. Laboratory HVAC and deionized water systems are designed to minimize potential trace contaminants.

The laboratory is separated into specific areas for sample receiving, sample preparation, volatile organic sample analysis, non-volatile organic sample analysis, inorganic sample analysis, microbiological sample analysis, and administrative functions.

18.2 Environment

Laboratory accommodation, test areas, energy sources, lighting are adequate to facilitate proper performance of tests. The facility is equipped with heating, ventilation, and air conditioning (HVAC) systems appropriate to the needs of environmental testing performed at this laboratory.

The environment in which these activities are undertaken does not invalidate the results or adversely affect the required accuracy of any measurements.

The laboratory provides for the effective monitoring, control and recording of environmental conditions that may affect the results of environmental tests as required by the relevant specifications, methods, and procedures. Such environmental conditions include humidity, voltage, temperature, and vibration levels in the laboratory. Systems are controlled and monitored to assure constant and consistent test conditions.

When any of the method or regulatory required environmental conditions change to a point where they may adversely affect test results, analytical testing will be discontinued until the environmental conditions are returned to the required levels.

Environmental conditions of the facility housing the computer network and TALS are regulated to protect against raw data loss.

When a laboratory performs laboratory activities at sites of facilities outside its permanent control, it shall ensure that the requirements related to facilities and environmental conditions of this document are met.

Specific requirements for facility and environmental conditions, as well as periodic monitoring of conditions, are given in the Environmental Health & Safety Manual plus each laboratory's Facility Addendum.

18.3 Work Areas

There is effective separation between neighboring areas when the activities therein are incompatible with each other. Examples include:

- Microbiological culture handling and sample incubation areas
- Volatile organic chemical handling areas, including sample preparation and waste disposal, and volatile organic chemical analysis areas

Access to and use of all areas affecting the quality of analytical testing is defined and controlled by secure access to the laboratory building as described below in the Building Security section.

Adequate measures are taken to ensure good housekeeping in the laboratory and to ensure that any contamination does not adversely affect data quality. These measures include regular cleaning to control dirt and dust within the laboratory. Work areas are available to ensure an unencumbered work area. Work areas include:

- Access and entryways to the laboratory
- Sample receipt areas
- Sample storage areas
- Chemical and waste storage areas
- Data handling and storage areas
- Sample processing areas
- Sample analysis areas

Refer to the following documents and procedures for specific requirements for microbiological laboratory facilities:

- Standard Methods, 9020B, Sec. 2
- TNI V1M5, 1.7.3.7.a

18.4 Floor Plan

A floor plan can be found in Appendix 1.

18.5 Building Security

Building keys and alarm codes are distributed to employees as necessary.

Visitors to the laboratory sign in and out in a visitor's logbook. A visitor is defined as any person who visits the laboratory who is not an employee of the laboratory. In addition to signing into the laboratory, the Environmental, Health and Safety Manual contains requirements for visitors

and vendors. There are specific safety forms that must be reviewed and signed. Visitors (with the exception of company employees) are escorted by laboratory personnel at all times, or the location of the visitor is noted in the visitor's logbook.

SECTION 19

TEST METHODS AND METHOD VALIDATION

19.1 Overview

The laboratory uses methods that are appropriate to meet our clients' requirements and that are within the scope of the laboratory's capabilities. These include sampling, handling, transport, storage and preparation of samples, and, where appropriate, an estimation of the measurement of uncertainty as well as statistical techniques for analysis of environmental data.

Instructions are available in the laboratory for the operation of equipment as well as for the handling and preparation of samples. All instructions, Standard Operating Procedures (SOPs), reference methods and manuals relevant to the working of the laboratory are readily available to all staff. Deviations from published methods are documented (with justification) in the laboratory's approved SOPs. SOPs are submitted to clients for review at their request. Significant deviations from published methods require client approval and regulatory approval where applicable.

19.2 Standard Operating Procedures (SOPs)

The laboratory maintains SOPs that accurately reflect all phases of the laboratory such as assessing data integrity, corrective actions, handling customer complaints as well as all analytical methods and sampling procedures. The method SOPs are derived from the most recently promulgated/approved, published methods and are specifically adapted to the laboratory facility. Modifications or clarifications to published methods are clearly noted in the SOPs. All SOPs are controlled in the laboratory. A SOP list is included in Appendix 4. The most current list of SOPs is maintained in the QA SOP directory, Work Instruction PT-QA-WI-002.

- All SOPs contain a revision number, effective date, and appropriate approval signatures. Controlled copies are available to all staff.
- Procedures for writing an SOP are incorporated by reference to Eurofins TestAmerica's Corporate SOP No. CW-Q-S-002, *Writing a Standard Operating Procedure*, or Pittsburgh SOP PT-QA-010, *Document Development and Control*.
- SOPs are reviewed at a minimum of every 2 years, and where necessary, revised to ensure continuing suitability and compliance with applicable requirements. SOPs related to drinking water testing are reviewed every year.

19.3 Laboratory Methods Manual

For each test method, the laboratory shall have available the published referenced method as well as the laboratory developed SOP.

Note: If more stringent standards or requirements are included in a mandated test method or regulation than those specified in this manual, the laboratory shall demonstrate that such

requirements are met. If it is not clear which requirements are more stringent, the standard from the method or regulation is to be followed. Any exceptions or deviations from the referenced methods or regulations are noted in the specific analytical SOP.

The laboratory maintains an SOP Index (PT-QA-WI-002) for both technical and non-technical SOPs. Technical SOPs are maintained to describe a specific test method. Non-technical SOPs are maintained to describe functions and processes not related to a specific test method.

19.4 Selection Of Methods

Since numerous methods and analytical techniques are available, continued communication between the client and laboratory is imperative to assure the correct methods are utilized. Once client methodology requirements are established, this and other pertinent information is summarized by the Project Manager. These mechanisms ensure that the proper analytical methods are applied when the samples arrive for log-in. For non-routine analytical services (e.g., special matrices, non-routine compound lists), the method of choice is selected based on client needs and available technology. The methods selected should be capable of measuring the specific parameter of interest, in the concentration range of interest, and with the required precision and accuracy.

19.4.1 Sources of Methods

Routine analytical services are performed using standard EPA-approved methodology. In some cases, modification of standard approved methods may be necessary to provide accurate analyses of particularly complex matrices. When the use of specific methods for sample analysis is mandated through project or regulatory requirements, only those methods shall be used.

When clients do not specify the method to be used or methods are not required, the methods used will be clearly validated and documented in an SOP and available to clients and/or the end user of the data.

The analytical methods used by the laboratory are those currently accepted and approved by the U. S. EPA and the state or territory from which the samples were collected. Reference methods include:

- *Guidelines Establishing Test Procedures for the Analysis of Pollutants Under the Clean Water Act; Analysis and Sampling Procedures; 40CFR Part 136 as amended by Method Update Rule, August 28, 2017*
- *Methods for Chemical Analysis of Water and Wastes, EPA 600 (4-79-020), 1983*
- *Methods for the Determination of Inorganic Substances in Environmental Samples, EPA-600/R-93/100, August 1993*
- *Methods for the Determination of Metals in Environmental Samples, EPA/600/4-91/010, June 1991. Supplement I: EPA-600/R-94/111, May 1994*
- *Standard Methods for the Examination of Water and Wastewater, 18th/19th /20th /on-line edition; Eaton, A.D. Clesceri, L.S. Greenberg, A.E. Eds; American Water Works Association, Water Pollution Control Federation, American Public Health Association: Washington, D.C.*
- *Test Methods for Evaluating Solid Waste Physical/Chemical Methods (SW846), Third Edition, September 1986, Final Update I, July 1992, Final Update IIA, August 1993, Final Update II,*

September 1994; Final Update IIB, January 1995; Final Update III, December 1996; Final Update IV, January 2008, Final Update V, August 2015

- *Annual Book of ASTM Standards, American Society for Testing & Materials (ASTM), Philadelphia, PA.*
- *Code of Federal Regulations (CFR) 40, Parts 136, 141, 172, 173, 178, 179 and 261*
- *Evaluation of Dredged Material Proposed for Disposal at Island, Nearshore, or Upland Confined Disposal Facilities – Testing Manual, U.S. Army Corps of Engineers, January, 2003*

The laboratory reviews updated versions to all the aforementioned references for adaptation based upon capabilities, instrumentation, etc., and implements them as appropriate. As such, the laboratory strives to perform only the latest versions of each approved method as regulations allow or require.

Other reference procedures for non-routine analyses may include methods established by specific states (e.g., Underground Storage Tank methods), ASTM or equipment manufacturers. Sample type, source, and the governing regulatory agency requiring the analysis will determine the method utilized.

The laboratory shall inform the client when a method proposed by the client may be inappropriate or out of date. After the client has been informed, and they wish to proceed contrary to the laboratory's recommendation, it will be documented.

19.4.2 Demonstration of Capability

Before the laboratory may institute a new method and begin reporting results, the laboratory shall confirm that it can properly operate the method. In general, this demonstration does not test the performance of the method in real world samples, but in an applicable and available clean matrix sample. If the method is for the testing of analytes that are not conducive to spiking, demonstration of capability may be performed on quality control samples.

A demonstration of capability (DOC) is performed whenever there is a change in instrument type (e.g., new instrumentation), matrix, method or personnel (e.g., analyst hasn't performed the test within the last 12 months). The IDOC must meet the control limits specified in the reference method, if any, or meet method LCS criteria if no IDOC specific controls are provided. (see laboratory SOP No. PT-QA-001, *Employee Orientation and Training*, for details)

Note: The laboratory shall have a DOC for all analytes included in the methods that the laboratory performs, and proficiency DOCs for each analyst shall include all analytes that the laboratory routinely performs. Addition of non-routine analytes does not require new DOCs for all analysts if those analysts are already qualified for routine analytes tested using identical chemistry and instrument conditions.

The initial demonstration of capability must be thoroughly documented and approved by the Technical Manager and QA Manager prior to independently analyzing client samples. All associated documentation must be retained in accordance with the laboratories archiving procedures.

The laboratory must have an approved SOP, demonstrate satisfactory performance, and conduct an MDL study (when applicable). There may be other requirements as stated within the published method or regulations (i.e., retention time window study).

Note: In some instances, a situation may arise where a client requests that an unusual analyte be reported using a method where this analyte is not normally reported. If the analyte is being reported for regulatory purposes, the method must meet all procedures outlined within this QA Manual (SOP, MDL, and DOC). If the client states that the information is not for regulatory purposes, the result may be reported as long as the following criteria are met:

- The instrument is calibrated for the analyte to be reported using the criteria for the method and ICV/CCV criteria are met (unless an ICV/CCV is not required by the method or criteria are per project DQOs).
- The laboratory's nominal or default reporting limit (RL) is equal to the quantitation limit (QL), must be at or above the lowest non-zero standard in the calibration curve and must be reliably determined. Project RLs are client specified reporting levels which may be higher than the QL. Results reported below the QL must be qualified as estimated values. Also see Section 19.6.1.3, Relationship of Limit of Detection (LOD) to Quantitation Limit (QL).
- The client request is documented and the lab informs the client of its procedure for working with unusual compounds. The final report must be footnoted: *Reporting Limit based on the low standard of the calibration curve.*

19.4.3 Initial Demonstration of Capability (IDOC) Procedures

Initial Demonstration and Capability (IDOC) procedure is described in laboratory SOP No. PT-QA-001.

19.4.3.1 The spiking standard used to prepare IDOCs must be prepared independently from those used in instrument calibration.

19.4.3.2 The analyte(s) shall be diluted in a volume of clean matrix sufficient to prepare four aliquots at the concentration specified by a method or the laboratory SOP.

19.4.3.3 At least four aliquots shall be prepared (including any applicable clean-up procedures) and analyzed according to the test method (either concurrently or over a period of days).

19.4.3.4 Using all of the results, calculate the mean recovery in the appropriate reporting units and the standard deviations for each parameter of interest.

19.4.3.5 When it is not possible to determine the mean and standard deviations, such as for presence/absence and logarithmic values, the laboratory will assess performance against criteria described in the method SOP.

19.4.3.6 Compare the information obtained above to the corresponding acceptance criteria for precision and accuracy in the test method (if applicable) or in the laboratory generated acceptance criteria (LCS or interim criteria) if there is no mandatory criteria established. If any one of the parameters do not meet the acceptance criteria, the performance is unacceptable for that parameter.

19.4.3.7 When one or more of the tested parameters fail at least one of the acceptance criteria, the analyst must proceed according to either option below:

- Locate and correct the source of the problem and repeat the test for all parameters of interest beginning with 19.4.3.3 above.
- Beginning with 19.4.3.3 above, repeat the test for all parameters that failed to meet criteria. Repeated failure, however, will confirm a general problem with the measurement system. If this occurs, locate and correct the source

of the problem and repeat the test for all parameters beginning with 19.4.3.1 above.

Note: Results of successive LCS analyses can be used to fulfill the DOC requirement.

A certification statement (Figure 19-1) shall be used to document the completion of each initial and continuing demonstration of capability. A copy of the certification is archived in the analyst's training file.

Methods on line prior to the effective date of this Section shall be updated to the procedures outlined above as new analysts perform their demonstration of capability. A copy of the new record will replace that which was used for documentation in the past. At a minimum, the precision and accuracy of four mid-level laboratory control samples must have been compared to the laboratory's quality control acceptance limits for methods for which standards exist.

19.5 Laboratory Developed Methods And Non-Standard Methods

Any new method developed by the laboratory must be fully defined in an SOP and validated by qualified personnel with adequate resources to perform the method. Method specifications and the relation to client requirements must be clearly conveyed to the client if the method is a non-standard method (not a published or routinely accepted method). The client must also be in agreement to the use of the non-standard method.

19.6 Validation Of Methods

Validation is the confirmation by examination and the provision of objective evidence that the particular requirements for a specific intended use are fulfilled. Validation of a method is a planned activity. A coordinator is designated for the process, who's responsibility it is to communicate the process and progress to all involved personnel.

All non-standard methods, laboratory designed/developed methods, standard methods used outside of their scope, and major modifications to published methods must be validated to confirm they are fit for their intended use. The validation will be as extensive as necessary to meet the needs of the given application. The results are documented with the validation procedure used and contain a statement as to the fitness for use.

19.6.1 Method Validation and Verification Activities for All New Methods

While method validation can take various courses, the following activities can be required as part of method validation. Method validation records are designated QC records and are archived accordingly.

When changes are made to any validated methods, the influence of such changes shall be documented and, if appropriate, a new validation shall be performed.

19.6.1.1 Determination of Method Selectivity

Method selectivity is the demonstrated ability to discriminate the analyte(s) of interest from other compounds in the specific matrix or matrices from other analytes or interference. In some

cases to achieve the required selectivity for an analyte, a confirmation analysis is required as part of the method.

19.6.1.2 Determination of Method Sensitivity

Sensitivity can be both estimated and demonstrated. Whether a study is required to estimate sensitivity depends on the level of method development required when applying a particular measurement system to a specific set of samples. Detection limit studies are conducted as described in Section 19.7 below. Where other protocols for estimations and/or demonstrations of sensitivity are required by regulation or client agreement, these shall be followed.

19.6.1.3 Relationship of Limit of Detection (LOD) to the Limit of Quantitation (LOQ)

An important characteristic of expression of sensitivity is the distinction between the LOD and the LOQ. The LOD is the minimum level at which the presence of an analyte can be reliably concluded. The LOQ is the minimum concentration of analyte that can be quantitatively determined with acceptable precision and bias, equivalent to the laboratory's routine reporting limit (RL). For most instrumental measurement systems, there is a region where semi-quantitative data is generated around the LOD (both above and below the estimated MDL or LOD) and below the LOQ. In this region, detection of an analyte may be confirmed but quantification of the analyte is unreliable within the accuracy and precision guidelines of the measurement system. When an analyte is detected below the LOQ, and the presence of the analyte is confirmed by meeting the qualitative identification criteria for the analyte, the analyte can be reliably reported, but the amount of the analyte can only be estimated. If data is to be reported in this region, it must be done so with a qualification that denotes the semi-quantitative nature of the result.

19.6.1.4 Determination of Interferences

A determination that the method is free from interferences in a blank matrix is performed.

19.6.1.5 Determination of Range

Where appropriate to the method, the quantitation range is determined by comparison of the response of an analyte in a curve to established or targeted criteria. Generally the upper quantitation limit is defined by highest acceptable calibration concentration. The lower quantitation limit or QL cannot be lower than the lowest non-zero calibration level, and can be constrained by required levels of bias and precision.

19.6.1.6 Determination of Accuracy and Precision

Accuracy and precision studies are generally performed using replicate analyses, with a resulting percent recovery and measure of reproducibility (standard deviation, relative standard deviation) calculated and measured against a set of target criteria.

19.6.1.7 Documentation of Method

The method is formally documented in an SOP. If the method is a minor modification of a standard laboratory method that is already documented in an SOP, an SOP Attachment describing the specific differences in the new method is acceptable in place of a separate SOP.

19.6.1.8 Continued Demonstration of Method Performance

Continued demonstration of Method Performance is addressed in the SOP. Continued demonstration of method performance is generally accomplished by batch specific QC samples such as LCS, method blanks or PT samples.

19.7 Method Detection Limits (MDL)/ Limits Of Detection (LOD)

The MDL is the minimum measured quantity of a substance that can be reported with 99% confidence that the concentration is distinguishable from method blank results, consistent with 40CFR Part 136 Appendix B, August, 2017. The MDL is equivalent to the TNI LOD, and is also equivalent to the DoD/DOE Quality Systems Manual (QSM) DL. The working or final MDL is the higher of the MDL value determined from spikes (MDLs) and the MDL value determined from blanks (MDLb). An initial MDL study shall be performed during the method validation process and when the method Is altered in a way that can reasonably be expected to change the sensitivity. On-going data are collected during each quarter in which samples are being analyzed. At least once every 13 months, the MDLs and MDLb are re-calculated and re-evaluated using data collected during the preceding period. Details of Eurofins TestAmerica's procedure for conducting MDL studies are given in SOP No. CA-Q-S-006.

19.8 Verification of Detection Limits

If it is found during the re-evaluation of detection limit results that more than 5% of the spiked samples do not return numeric results that meet the method qualitative identification criteria, then the spiking level shall be increased and the initial MDL study re-performed at the new spiking concentration.

19.9 Instrument Detection Limits (IDL)

The IDL is sometimes used to assess the reasonableness of the MDLs or in some cases required by the analytical method or program requirements. IDLs are most used in metals analyses but may be useful in demonstration of instrument performance in other areas.

IDLs are calculated to determine an instrument's sensitivity independent of any preparation method. IDLs are calculated either using 7 replicate spike analyses, like MDL but without sample preparation, or by the analysis of 10 instrument blanks and calculating 3 x the absolute value of the standard deviation.

19.10 Limit of Quantitation

The LOQ shall be at a concentration equivalent to the lowest calibration standard concentration, with the exception of methods using a single-point calibration, and shall be greater than the MSL. The LOQ is verified by preparing and analyzing spikes at or below the LOQ concentration, employing the complete analytical process.

When the laboratory establishes a quantitation limit, it must be initially verified by the analysis of two low level standards or QC samples at the reporting limit and quarterly thereafter. The laboratory will comply with any additional regulatory requirements.

19.11 Retention Time Windows

Most organic analyses and some inorganic analyses use chromatography techniques for qualitative and quantitative determinations. For every chromatography analysis or as specific in

the reference method, each analyte will have a specific time of elution from the column to the detector. This is known as the analyte's retention time. The variance in the expected time of elution is defined as the retention time window. As the key to analyte identification in chromatography, retention time windows must be established on every column for every analyte used for that method. These records are kept on-file and available for review. Complete details are available in the laboratory SOPs.

19.12 Evaluation Of Selectivity

The laboratory evaluates selectivity by following the checks within the applicable analytical methods, which include mass spectral tuning, second column confirmation, ICP interelement interference checks, chromatography retention time windows, sample blanks, spectrochemical, atomic absorption or fluorescence profiles, co-precipitation evaluations and specific electrode response factors.

19.13 Estimation Of Uncertainty Of Measurement

19.13.1 Uncertainty is "a parameter associated with the result of a measurement, that characterizes the dispersion of the values that could reasonably be attributed to the measurand" (as defined by the International Vocabulary of Basic and General Terms in Metrology, ISO Geneva, 1993, ISBN 92-67-10175-1). Knowledge of the uncertainty of a measurement provides additional confidence in a result's validity. Its value accounts for all the factors which could possibly affect the result, such as adequacy of analyte definition, sampling, matrix effects and interferences, climatic conditions, variances in weights, volumes, and standards, analytical procedure, and random variation. Some national accreditation organizations require the use of an "expanded uncertainty" defined as the range within which the value of the measurand is believed to lie within at least a 95% confidence level with the coverage factor k=2.

19.13.2 Uncertainty is not error. Error is a single value (i.e. the difference between the true result and the measured result). On environmental samples, the true result is never known. The measurement is the sum of the unknown true value and the unknown error. Unknown error is a combination of systematic error, or bias, and random error. Bias varies predictably, constantly, and independently from the number of measurements. Random error is unpredictable, assumed to be Gaussian in distribution, and reducible by increasing the number of measurements.

19.13.3 The minimum uncertainty associated with results generated by the laboratory can be determined by using the Laboratory Control Sample (LCS) accuracy range for a given analyte. The LCS limits are used to assess the performance of the measurement system since they take into consideration all of the laboratory variables associated with a given test over time (except for variability associated with the sampling and the variability due to matrix effects). The percent recovery of the LCS is compared either to the method-required LCS accuracy limits or to the statistical, historical, in-house LCS accuracy limits.

19.13.4 To calculate the uncertainty for the specific result reported, multiply the result by the decimal of the lower end of the LCS range percent value for the lower end of the uncertainty range, and multiply the result by the decimal of the upper end of the LCS range percent value for the upper end of the uncertainty range. These calculated values represent uncertainties at approximately the 99% confidence level with a coverage factor of k =3. As an example, for a reported result of 1.0 mg/L with an LCS recovery range of 50 to 150%, the estimated uncertainty

in the result would be 1.0 +/- 0.5 mg/L. Uncertainty determination is further described in laboratory SOP PT-QA-005, *Measurement Uncertainty*.

19.13.5 In the case where a well recognized test method specifies limits to the values of major sources of uncertainty of measurement and specifies the form of presentation of calculated results, no further discussion of uncertainty is required.

19.14 Sample Reanalysis Guidelines

Because there is a certain level of uncertainty with any analytical measurement, a sample re-preparation (where appropriate) and subsequent analysis (hereafter referred to as 'reanalysis') may result in either a higher or lower value from an initial sample analysis. There are also variables that may be present (e.g., sample homogeneity, analyte precipitation over time, etc.) that may affect the results of a reanalysis. Based on the above comments, the laboratory will reanalyze samples at a client's request with the following caveats. **Client specific Contractual Terms & Conditions for reanalysis protocols may supersede the following items.**

- Homogenous samples: If a reanalysis agrees with the original result to within the RPD limits for MS/MSD or Duplicate analyses, or within $\pm$ 1 reporting limit for samples $\leq$ 5x the reporting limit, the original analysis will be reported. At the client's request, both results may be reported.
- If the reanalysis does not agree (as defined above) with the original result, then the laboratory will investigate the discrepancy and reanalyze the sample a third time for confirmation if sufficient sample is available.
- Any potential charges related to reanalysis are discussed in the contract terms and conditions or discussed at the time of the request. The client will typically be charged for reanalysis unless it is determined that the lab was in error.
- Due to the potential for increased variability, reanalysis may not be applicable to Non-homogenous, Encore, and Sodium Bisulfate preserved samples. See the Area Technical Manager/Supervisor or Laboratory Director if unsure.

19.15 Control Of Data

The laboratory has policies and procedures in place to ensure the authenticity, integrity, and accuracy of the analytical data generated by the laboratory.

19.15.1 Computer and Electronic Data Related Requirements

The three basic objectives of our computer security procedures and policies are shown below. The laboratory is currently using the Eurofins TestAmerica TALS LIMS system, which has been highly customized to meet the needs of the laboratory. It is referred ti as TALS throughout this document. More setailed descriptions of computer systems and associated controls are given in the IT Change Control Procedure Manual (CW-I-M-001) and policies and procedures posted on Eurofins TestAmerica's Intranet site, Oasis.

19.15.1.1 **Maintain the Database Integrity:** Assurance that data is reliable and accurate through data verification (review) procedures, password-protecting access, anti-virus protection, data change requirements, as well as an internal LIMS permissions procedure.

- LIMS Database Integrity is achieved through data input validation, internal user controls, documentation of system failures and corrective actions taken, and data change requirements.
- Spreadsheets and other software developed in-house must be verified with documentation through hand calculations prior to use. Cells containing calculations must be lock-protected and controlled.
- Instrument hardware and software adjustments are safeguarded through maintenance logs, audit trails and controlled access.

19.15.1.2 **Ensure Information Availability:** Protection against loss of information or service is ensured through scheduled back-ups, stable file server network architecture, secure storage of media, line filter, Uninterruptible Power Supply (UPS), and maintaining older versions of software as revisions are implemented.

19.15.1.3 **Maintain Confidentiality:** Ensure data confidentiality through physical access controls such as password protection or website access approval, when electronically transmitting data.

19.15.2 Data Reduction

The complexity of the data reduction depends on the analytical method and the number of discrete operations involved (e.g., extractions, dilutions, instrument readings and concentrations). The analyst calculates the final results from the raw data or uses appropriate computer programs to assist in the calculation of final reportable values.

For manual data entry, e.g., Wet Chemistry, the data is reduced by the analyst and then verified by the Department Manager or alternate analyst prior to updating the data in TALS. The spreadsheets, or any other type of applicable documents, are signed by both the analyst and alternate reviewer to confirm the accuracy of the manual entry(s). The applicable data/spreadsheet is scanned in TALS with the batch.

Manual integration of peaks will be documented and reviewed and the raw data will be flagged in accordance with the Eurofins TestAmerica Corporate SOP No. CA-Q-S-002, *Acceptable Manual Integration Practices*.

Analytical results are reduced to appropriate concentration units specified by the analytical method, taking into account factors such as dilution, sample weight or volume, etc. Blank correction will be applied only when required by the method or per manufacturer's indication; otherwise, it should not be performed. Calculations are independently verified by appropriate laboratory staff. Calculations and data reduction steps for various methods are summarized in the respective analytical SOPs or program requirements.

19.15.2.1 All raw data must be retained in the worklist folder, computer file (if appropriate), and/or run log. All criteria pertinent to the method must be recorded. The documentation is recorded at the time observations or calculations are made and must be signed or initialed/dated (month/day/year). It must be easily identifiable who performed which tasks if multiple people were involved.

19.15.2.2 In general, concentration results are reported in milligrams per liter (mg/l) or micrograms per liter (µg/l) for liquids and milligrams per kilogram (mg/kg) or micrograms per

kilogram (µg/kg) for solids. For values greater than 10,000 mg/l, results can be reported in percent, i.e., 10,000 mg/l = 1**%.** Units are defined in each lab SOP.

19.15.2.3 In reporting, the analyst or the instrument output records the raw data result using values of known certainty plus one uncertain digit. If final calculations are performed external to TALS, the results should be entered in LIMS with at least three significant figures. In general, results are reported to 2 significant figures on the final report.

19.15.2.4 For those methods that do not have an instrument printout or an instrumental output compatible with TALS, the raw results and dilution factors are entered directly into TALS by the analyst, and the software calculates the final result for the analytical report. TALS has a defined significant figure criterion for each analyte.

19.15.2.5 The laboratory strives to import data directly from instruments or calculation spreadsheets to ensure that the reported data are free from transcription and calculation errors. For those analyses with an instrumental output compatible with the TALS, the raw results and dilution factors are transferred into TALS electronically after reviewing the quantitation report, and removing unrequested or poor spectrally-matched compounds. The analyst prints a copy of what has been entered to check for errors. This printout and the instrument's printout of calibrations, concentrations, retention times, chromatograms, and mass spectra, if applicable, are retained with the data file. The data file is stored on the server and every night backed up to a tape file.

19.15.3 Logbook / Worksheet Use Guidelines

Logbooks and worksheets are filled out 'real time' and have enough information on them to trace the events of the applicable analysis/task. (e.g. calibrations, standards, analyst, sample ID, date, time on short holding time tests, temperatures when applicable, calculations are traceable, etc.)

- Corrections are made following the procedures outlined in Section 12.
- Logbooks are controlled by the QA department. A record is maintained of all logbooks in the lab.
- Unused portions of pages must be "Z"'d out, signed and dated.
- Worksheets are created with the approval of the Technical Manager / QA Manager at the facility.
  - Any cells that perform calculations must have the calculation verified and the cell locked so that the formula cannot be changed.
  - The QA Manager controls all worksheets following the procedures in Section 6.

19.15.4 Review / Verification Procedures

Review procedures are outlined in several SOPs (e.g. laboratory SOPs PT-QA-013, *Independent QA Data Review*; PT-QA-018, *Technical Data Review*; and PT-SR-001, *Sample Receipt and Login*) to ensure that reported date are free from calculation and transcription errors, and that QC parameters have been reviewed and evaluated before data is reported. The laboratory also has an SOP discussing Manual Integrations to ensure the authenticity of the data (CA-Q-S-002). The general review concepts are discussed below. More specific information can be found in the SOPs.

19.15.4.1 Log-In Review - The data review process starts at the sample receipt stage. Sample control personnel review chain-of-custody forms and project instructions from the project management group. This is the basis of the sample information and analytical instructions entered into the TALS. The log-in instructions are reviewed by the personnel entering the information, and a second level review is conducted by the project management staff.

19.15.4.2 First Level Data Review - The next level of data review occurs with the analysts. As data are generated, analysts review their work to ensure that the results meet project and SOP requirements. First level reviews include inspection of all raw data (e.g., instrument output for continuous analyzers, chromatograms, spectra, and manual integrations), evaluation of calibration/calibration verification data in the day's analytical run, evaluation of QC data, documentation of standards and reagents, and reliability of sample results. The analyst transfers data into TALS, data qualifiers are added as needed. All first level reviews are documented.

19.15.4.3 Second Level Data Review – All analytical data are subject to review by a second qualified analyst or supervisor. Second level reviews include inspection of all raw data (e.g., instrument output, chromatograms, and spectra) including 100% of data associated with any changes made by the primary analyst, such as manual integrations or reassignment of peaks to different analytes, or elimination of false negative analytes. The second review also includes evaluation of initial calibration/calibration verification data in the day's analytical run, evaluation of QC data, documentation of standards and reagents, reliability of sample results, qualifiers and NCM narratives. Manual calculations are checked in second level review. All second level reviews are documented.

Issues that deem further review include the following:

- QC data are outside the specified control limits for accuracy and precision
- Reviewed sample data does not match with reported results
- Unusual detection limit changes are observed
- Samples having unusually high results
- Samples exceeding a known regulatory limit
- Raw data indicating some type of contamination or poor technique
- Inconsistent peak integration
- Transcription errors
- Results outside of calibration range

19.15.4.4 Unacceptable analytical results may require reanalysis of the samples. Any problems are brought to the attention of the Laboratory Director, Project Manager, Quality Assurance Manager, Technical Director, Department Manager or section Supervisor for further investigation. Corrective action is initiated whenever necessary.

19.15.4.5 The results are then entered or directly transferred into the computer database and a hard copy (or .pdf) is printed for the client.

19.15.4.6 As a final review prior to the release of the report, the Project Manager (or designee) reviews the results for appropriateness and completeness. This review and approval ensures that client requirements have been met and that the final report has been properly

completed. The process includes, but is not limited to, verifying that the COC is followed, cover letters/ narratives are present, flags are appropriate, and project specific requirements are met. The Project Manager may also evaluate the validity of results for different test methods given expected chemical relationships.

19.15.4.7 Any project that requires a data package is subject to a tertiary data review for transcription errors and acceptable quality control requirements. The Project Manager (or designee) then signs the final report. They also check the report for any clerical or invoicing errors. When complete, the report is sent out to the client.

19.15.4.8 As a further check of the system, the QA department reviews both selected and random analytical batches and final reports.

19.15.4.9 A visual summary of the flow of samples and information through the laboratory, as well as data review and validation, is presented in Figure 19-2.

19.15.5 Manual Integrations

Computerized data systems provide the analyst with the ability to re-integrate raw instrument data in order to optimize the interpretation of the data. Though manual integration of data is an invaluable tool for resolving variations in instrument performance and some sample matrix problems, when used improperly, this technique would make unacceptable data appear to meet quality control acceptance limits. Improper re-integrations lead to legally indefensible data, a poor reputation, or possible laboratory decertification. Because guidelines for re-integration of data are not provided in the methods and most methods were written prior to widespread implementation of computerized data systems, the laboratory trains all analytical staff on proper manual integration techniques using Corporate SOP No. CA-Q-S-002.

19.15.5.1 The analyst must adjust baseline or the area of a peak in some situations, for example when two compounds are not adequately resolved or when a peak shoulder needs to be separated from the peak of interest. The analyst must use professional judgment to determine when manual integrating is required. Analysts are encouraged to ask for assistance from a senior analyst or manager when in doubt.

19.15.5.2 Analysts shall not increase or decrease peak areas for the sole purpose of achieving acceptable QC recoveries that would have otherwise been unacceptable. The intentional recording or reporting of incorrect information (or the intentional omission of correct information) is against company principles and policy and is grounds for immediate termination.

19.15.5.3 Client samples, performance evaluation samples, and quality control samples are all treated equally when determining whether or not a peak area or baseline should be manually adjusted.

19.15.5.4 All manual integrations receive a second level review. Manual integrations must be indicated on an expanded scale “before” and “after” chromatograms such that the integration performed can be easily evaluated during data review. Expanded scale “before” chromatograms are also required for all manual integrations on QC parameters (calibrations, calibration verifications, laboratory control samples, internal standards, surrogates, etc.) unless the laboratory has another documented Corporate approved procedure in place that can demonstrate an active process for detection and deterrence of improper integration practices.

Certification Statement:

We, the undersigned, certify that:

1. The analyst identified above, using the cited test method with the specifications in the cited SOP, which is in use at this facility for the analysis of samples under the laboratory's Quality Assurance Plan, has completed the Demonstration of Capability (DOC).
2. The test method(s) was performed by the analyst identified on this certificate.
3. A copy of the test method and the laboratory-specific SOPs are available for all personnel on site. These documents have been reviewed by the analyst as part of this DOC.
4. The data associated with the demonstration of capability are true, accurate, complete, and self-explanatory.
5. All raw data necessary to reconstruct and validate these analyses have been retained at the facility, and the associated information is well organized and available for review.

SECTION 20

EQUIPMENT AND CALIBRATIONS

20.1 Overview

The laboratory purchases the most technically advanced analytical instrumentation for sample analyses. Instrumentation is purchased on the basis of accuracy, dependability, efficiency and sensitivity. Each laboratory is furnished with all items of sampling, preparation, analytical testing and measurement equipment necessary to correctly perform the tests for which the laboratory has capabilities. Each piece of equipment is capable of achieving the required accuracy and complies with specifications relevant to the method being performed. Before being placed into use, the equipment (including sampling equipment) is calibrated and checked to establish that it meets its intended specification. The calibration routines for analytical instruments establish the range of quantitation. Calibration procedures are specified laboratory analytical SOPs. Also see Corporate Policy No. CA-Q-P-003, *Calibration Curves and Selection of Calibration Points*.

A list of laboratory instrumentation types is presented in Table 20-1.

Equipment is only operated by authorized and trained personnel. Manufacturer's instructions for equipment use are readily accessible to all appropriate laboratory personnel.

20.2 Preventive Maintenance

The laboratory follows a well-defined maintenance program to ensure proper equipment operation and to prevent the failure of laboratory equipment or instrumentation during use. This program of preventive maintenance helps to avoid delays due to instrument failure.

Routine preventive maintenance procedures and frequency, such as cleaning and replacements, should be performed according to the procedures outlined in the manufacturer's manual. Qualified personnel must also perform maintenance when there is evidence of degradation of peak resolution, a shift in the calibration curve, loss of sensitivity, or failure to continually meet one of the quality control criteria.

Table 20-2 lists examples of scheduled routine maintenance. It is the responsibility of each Technical Manager to ensure that instrument maintenance logs are kept for all equipment in his/her department. Preventative maintenance procedures are outlined in analytical SOPs or instrument manuals. Further detail for equipment maintenance is included in SOP No. PT-QA-022 and individual analytical SOPs. (Note: for some equipment, the log used to monitor performance is also the maintenance log. Multiple pieces of equipment may share the same log as long as it is clear as to which instrument is associated with an entry.)

Instrument maintenance logs are controlled and are used to document instrument problems, instrument repair and maintenance activities. Maintenance logs shall be kept for all major pieces of equipment. Instrument maintenance logs may also be used to specify instrument parameters.

- Documentation must include all major maintenance activities such as contracted preventive maintenance and service and in-house activities such as the replacement of electrical components, lamps, tubing, valves, columns, detectors, cleaning and adjustments.

- Each entry in the instrument log includes the Analyst's initials, the date, a detailed description of the problem (or maintenance needed/scheduled), a detailed explanation of the solution or maintenance performed, and a verification that the equipment is functioning properly (state what was used to determine a return to control. e.g. CCV run on *'date'* was acceptable, or instrument recalibrated on 'date' with acceptable verification, etc.) must also be documented in the instrument records.

- When maintenance or repair is performed by an outside agency, service receipts detailing the service performed can be affixed into the logbooks adjacent to pages describing the maintenance performed. This attached document must be signed across the page entered and the logbook so that it is clear that a page is missing if only half a signature is found in the logbook.

If an instrument requires repair (subjected to overloading or mishandling, gives suspect results, or otherwise has shown to be defective or outside of specified limits) it shall be taken out of operation and tagged as out-of-service or otherwise isolated until such a time as the repairs have been made and the instrument can be demonstrated as operational by calibration and/or verification or other test to demonstrate acceptable performance. The laboratory shall examine the effect of this defect on previous analyses.

In the event of equipment malfunction that cannot be resolved, service shall be obtained from the instrument vendor manufacturer, or qualified service technician, if such a service can be tendered. If on-site service is unavailable, arrangements shall be made to have the instrument shipped back to the manufacturer for repair. Back-up instruments, which have been approved, for the analysis shall perform the analysis normally carried out by the malfunctioning instrument. If the back-up is not available and the analysis cannot be carried out within the needed timeframe, the samples shall be subcontracted.

If an instrument is sent out for service or transferred to another facility, it must be recalibrated and the laboratory MDL verified prior to return to lab operations following the requirements in SOP PT-QA-007.

20.3 Support Equipment

This section applies to all devices that may not be the actual test instrument, but are necessary to support laboratory operations. These include but are not limited to: balances, ovens, refrigerators, freezers, incubators, water baths, field sampling devices, temperature measuring devices, thermal/pressure sample preparation devices and volumetric dispensing devices if quantitative results are dependent on their accuracy, as in standard preparation and dispensing or dilution into a specified volume. All raw data records associated with the support equipment are retained to document instrument performance.

Support equipment that provides quantitative results are calibrated or calibration verified to a recognized national metrology standard, such as NIST, where available, over the expected range of use. The acceptability for use shall be according to the needs of the analysis or application for which the equipment is being used.

Calibration and calibration verification scheduling and documentation for support equipment is maintained by the QA department. All equipment is labeled with the most recent calibration information and the next verification due date.

20.3.1 Weights and Balances

The accuracy of the balances used in the laboratory is checked every working day, before use. All balances are placed on stable counter tops.

Each balance is checked prior to initial serviceable use with at least three certified ASTM type 1 weights spanning its range of use (weights that have been calibrated to ASTM type 1 weights may also be used for daily verification). ASTM type 1 weights used only for calibration of other weights (and no other purpose) are inspected for corrosion, damage or nicks at least annually and if no damage is observed, they are calibrated at least every 5 years by an outside calibration laboratory. Any weights (including ASTM Type 1) used for daily balance checks or other purposes are recalibrated/recertified annually to NIST standards (this may be done internally if laboratory maintains "calibration only" ASTM type 1 weights).

All balances are serviced annually by a qualified service representative, who supplies the laboratory with a certificate that identifies traceability of the calibration to the NIST standards.

All of this information is recorded in logs, and the recalibration/recertification certificates are kept on file. Refer to Pittsburgh Laboratory SOP No. PT-QA-012, *Selection and Calibration of Balances and Weights*, for details.

20.3.2 pH, Conductivity, and Turbidity Meters

The pH meters used in the laboratory are accurate to ± 0.1 pH units, and have a scale readability of at least 0.05 pH units. The meters automatically compensate for the temperature, and are calibrated with at least two working range buffer solutions before each use.

Conductivity meters used in the laboratory are capable of measuring conductivity with an error not exceeding 1% or one umhos/cm, whichever is greater. The meters are also calibrated before each use with a known standard.

Turbidity meters are also calibrated before each use. All of this information is documented in logs.

Consult pH and Conductivity, and Turbidity laboratory analytical SOPs for further information.

20.3.3 Thermometers

All thermometers are calibrated on an annual basis with a NIST-traceable thermometer. IR thermometers, digital probes and thermocouples are calibrated quarterly. IR thermometers are checked daily for calibration accuracy against an NIST thermometer daily before use.

- If the temperature measuring device is used over a range of 10℃ or less, then a single point verification within the range of use is acceptable;
- If the temperature measuring device is used over a range of greater than 10℃, then the verification must bracket the range of use.

IR thermometers, digital probes and thermocouples are calibrated quarterly.

Mercury or digital NIST thermometers are recalibrated every five years (unless thermometer has been exposed to temperature extremes or apparent separation of internal liquid) by an approved outside service and the provided certificate of traceability is kept on file. The NIST

thermometer(s) have increments of at least 1 degree (0.5 degree or less increments are required for drinking water microbiological laboratories), and have ranges applicable to method and certification requirements. The NIST traceable thermometers are used for no other purpose than to calibrate other thermometers.

All of this information is documented in logbooks. Monitoring method-specific temperatures, including incubators, heating blocks, water baths, and ovens, is documented in method or device-specific logbooks. More information on this subject can be found in Pittsburgh Laboratory SOP No. PT-QA-008, *Thermometer and Barometer Verification and Temperature Monitoring*.

20.3.4 Refrigerators/Freezer Units, Waterbaths, Ovens and Incubators

The temperatures of all refrigerator units and freezers used for sample and standard storage are monitored each working day. Sample storage temperatures are monitored continuously (24/7).

Ovens, waterbaths and incubators are monitored on days of use.

All of this equipment has a unique identification number, and is assigned a thermometer for monitoring.

Sample storage refrigerator temperatures are kept between > 0ºC and ≤ 6 ºC.

Specific temperature settings/ranges for other refrigerators, ovens waterbaths, and incubators can be found in method specific SOPs.

All of this information is documented in Daily Temperature Logbooks or electronically. Refer to laboratory SOP PT-QA-008.

20.3.5 Autopipettors, Dilutors, and Syringes

Mechanical volumetric dispensing devices, including burettes, (except Class A Glassware and glass microliter syringes) are given unique identification numbers and the delivery volumes are verified gravimetrically, at a minimum, on a quarterly basis. Glass micro-syringes are considered the same as Class A glassware.

For those dispensers that are not used for analytical measurements, a label shall be applied to the device stating that it is not calibrated. Any device not regularly verified cannot be used for any quantitative measurements. Pipette calibration is described in Pittsburgh Laboratory SOP No. PT-QA-017, *Aqueous Pipette Calibration*.

Micro-syringes are purchased from Hamilton Company. Each syringe is traceable to NIST. The laboratory keeps on file an “Accuracy and Precision Statement of Conformance” from Hamilton attesting established accuracy.

20.3.6 Field Sampling Devices (Isco Auto Samplers)

Each Auto Sampler (ISCO) is assigned a unique identification number in order to keep track of the calibration. This number is also recorded on the sampling documentation.

The Auto Sampler is calibrated quarterly by setting the sample volume to 100ml and recording the volume received. The results are filed in a logbook/binder. The Auto Sampler is programmed to run three (3) cycles and each of the three cycles is measured into a graduated cylinder to verify 100ml are received.

If the RSD (Relative Standard Deviation) between the 3 cycles is greater than 10%, the procedure is repeated and if the result is still greater than 10%, then the Auto Sampler is taken out of service until it is repaired and calibration verification criteria can be met. The results of this check are kept in a logbook/binder.

20.4 Instrument Calibrations

Calibration of analytical instrumentation is essential to the production of quality data. Strict calibration procedures are followed for each method. These procedures are designed to determine and document the method detection limits, the working range of the analytical instrumentation and any fluctuations that may occur from day to day.

Sufficient raw data records are retained to allow an outside party to reconstruct all facets of the initial calibration. Records contain, but are not limited to, the following: calibration date, method, instrument, analyst(s) initials or signatures, analysis date, analytes, concentration, response, type of calibration (Avg RF, curve, or other calculations that may be used to reduce instrument responses to concentration.)

Sample results must be quantitated from the initial calibration and may not be quantitated from any continuing instrument calibration verification unless otherwise required by regulation, method or program.

If the initial calibration results are outside of the acceptance criteria, corrective action is performed and any affected samples are reanalyzed if possible. If the reanalysis is not possible, any data associated with an unacceptable initial calibration will be reported with appropriate data qualifiers (refer to Section 12).

Note: Instruments are calibrated initially and as needed after that and at least annually.

20.4.1 Calibration Standards

Calibration standards are prepared using the procedures indicated in the Reagents and Standards section of the determinative method SOP. If a reference method does not specify the number of calibration standards, a minimum of 3 calibration points (exception being ICP and ICP/MS methods) will be used.

Standards for instrument calibration are obtained from a variety of sources. All standards are traceable to national or international standards of measurement, or to national or international standard reference materials.

The lowest concentration calibration standard that is analyzed during an initial calibration must be at or below the stated reporting limit for the method based on the final volume of extract (or sample).

The other concentrations define the working range of the instrument/method or correspond to the expected range of concentrations found in actual samples that are also within the working

range of the instrument/method. Results of samples not bracketed by initial instrument calibration standards (within calibration range to at least the same number of significant figures used to report the data) must be reported as having less certainty, e.g., defined qualifiers or flags (additional information may be included in the case narrative). The exception to these rules is ICP and ICP-MS methods or other methods which define the working range with periodic linear dynamic range studies, rather than through the range of concentrations of daily calibration standards.

All initial calibrations are verified with a standard obtained from a second source and traceable to a national standard, when available (or vendor certified different lot if a second source is not available). For unique situations, such as air analysis where no other source or lot is available, a standard made by a different analyst at a different time or by a different preparation would be considered a second source. This verification occurs immediately after the calibration curve has been analyzed, and before the analysis of any samples.

20.4.1.1 Calibration Verification

The calibration relationship established during the initial calibration must be verified at least daily as specified in the laboratory method SOPs in accordance with the referenced analytical methods and in the 2009 and 2016 TNI standard. The process of calibration verification applies to both external standard and internal standard calibration techniques, as well as to linear and non-linear calibration models. Initial calibration verification (ICV) is with a standard source secondary (second source standard) to the calibration standards, but continuing calibration verifications (CCV) may use the same source standards as the calibration curve.

Note: The process of calibration verification referred to is fundamentally different from the approach called "calibration" in some methods. As described in those methods, the calibration factors or response factors calculated during calibration are used to update the calibration factors or response factors used for sample quantitation. This approach, while employed in other EPA programs, amounts to a daily single-point calibration.

All target analytes and surrogates, including those reported as non-detects, must be included in periodic calibration verifications for purposes of retention time confirmation and to demonstrate that calibration verification criteria are being met, i. e., RPD, per 2009 TNI Std. EL-V1M4 Sec. 1.7.2.

All samples must be bracketed by periodic analyses of standards that meet the QC acceptance criteria (e.g., calibration and retention time). The frequency is found in the determinative methods or SOPs.

Generally, the initial calibrations must be verified by an ICV analyzed immediately following initial calibration and before sample analysis. The ICV may be used as the first bracketing CCV if criteria for both are met.

A continuing instrument calibration verification (CCV) is generally analyzed at the beginning of each 12-hour analytical shift during which samples are analyzed. (The 12-hour analytical shift begins with the injection of the calibration verification standard (or the MS tuning standard is MS methods). The shift ends after the completion of the analysis of the last sample, QC, or standard that can be injected within 12 hours of the beginning of the shift. For methods that have quantitation by external calibration models, a CCV is analyzed at the end of each analytical sequence. Some methods have more frequent CCV requirements see specific SOPs.

Most Inorganic methods require the CCV to be analyzed after every 10 samples or injections, including matrix or batch QC samples.

Note: If an internal standard calibration is being used (e.g., GCMS and some GC methods) then bracketing standards are not required, only daily verifications are needed, except as specified by program or method requirements.

If the results of a CCV are outside the established acceptance criteria and analysis of a second consecutive (and immediate) CCV fails to produce results within acceptance criteria, corrective action shall be performed. Once corrective actions have been completed & documented, the laboratory shall demonstrate acceptable instrument / method performance by analyzing two consecutive CCVs, or a new initial instrument calibration shall be performed.

Sample analyses and reporting of data may not occur or continue until the analytical system is calibrated or calibration verified. However, data associated with a unacceptable calibration verification may be fully useable and may be reported, based upon discussion and approval of the client, under the following special conditions:

a) When the acceptance criteria for the CCV are exceeded high (i.e., high bias) and the associated samples within the batch are non-detects, then those non-detects may be reported with a footnote or case narrative comment explaining the high bias. Otherwise the samples affected by the unacceptable CCV shall be re-analyzed after a new calibration curve has been established, evaluated and accepted; or

b) When the acceptance criteria for the CCV are exceeded low (i.e., low bias), samples affected by the unacceptable CCV shall be re-analyzed after a new calibration curve has been established, evaluated and accepted.

Samples reported under one of the conditions identified above will be appropriately flagged.

20.4.1.2 Verification of Linear and Non-Linear Calibrations

Calibration verification for calibrations involves the calculation of the percent drift or the percent difference of the instrument response between the initial calibration and each subsequent analysis of the verification standard. (These calculations are available in the laboratory method SOPs.) Verification standards are evaluated based on the % Difference from the average CF or RF of the initial calibration or based on %Drift or %Recovery if a linear or quadratic curve is used.

Regardless of whether a linear or non-linear calibration model is used, if initial verification criterion is not met, then no sample analyses may take place until the calibration has been verified or a new initial calibration is performed that meets the specifications listed in the method SOPs. If the calibration cannot be verified after the analysis of a single verification standard, then adjust the instrument operating conditions and/or perform instrument maintenance, and analyze another aliquot of the verification standard. If the calibration cannot be verified with the second standard, then a new initial calibration is performed.

- When the acceptance criteria for the calibration verification are exceeded high, i.e., high bias, and there are associated samples that are non-detects, then those non-detects may be reported. Otherwise, the samples affected by the unacceptable calibration verification shall be reanalyzed after a new calibration curve has been established, evaluated and accepted.

- When the acceptance criteria for the calibration verification are exceeded low, i.e., low bias, those samples affected by the unacceptable verification shall be reanalyzed after a new calibration curve has been established, evaluated and accepted. Alternatively, a reporting limit standard may be analyzed to demonstrate that the laboratory can still support non-detects at their reporting limit.

Note: Some programs require additional verification steps for linear and quadratic calibration – i.e. reading the lowest, or all, initial calibration level standard against the curve, or verification at a low and a high concentration. See analytical SOPs and project notes for details.

20.5 Tentatively Identified Compounds (TICs) – GC/MS Analysis

For samples containing components not associated with the calibration standards, a library search may be made for the purpose of tentative identification. The necessity to perform this type of identification will be determined by the purpose of the analyses being conducted. Data system library search routines should not use normalization routines that would misrepresent the library or unknown spectra when compared to each other. Further details are given in policy memorandum CA-Q-QM-001, Policy on Tentatively Identified Compounds (TICs) – GC/MS Analysis.

Note: If the TIC compound is not part of the client target analyte list but is calibrated by the laboratory and is both qualitatively and/or quantitatively identifiable, it should not be reported as a TIC. If the compound is reported on the same form as true TICs, it should be qualified and/or narrated that the reported compound is qualitatively and quantitatively (if verification in control) reported compared to a known standard that is in control (where applicable).

20.6 GC/MS TUNING

Prior to any GCMS analytical sequence, including calibration, the instrument parameters for the tune and subsequent sample analyses within that sequence must be set.

Prior to tuning/auto-tuning the mass spectrometer the parameters may be adjusted within the specifications set by the manufacturer or the analytical method. These generally don't need any adjustment but it may be required based on the current instrument performance. If the tune verification does not pass it may be necessary to clean the source or perform additional maintenance. Any maintenance is documented in the maintenance log.

Table 20-1

Eurofins TestAmerica Pittsburgh Instrumentation Type List
(see PT-QA-WI-045 for the most current full listing of instrumentation and equipment)

Tables 20-2

Example - Schedule of Routine Maintenance
(See SOP No. PT-QA-022 for more instrument specific information)

Daily	Weekly	Monthly	Quarterly	Annually	As Needed
Check sample waste container level.	Check peristaltic pump: proper roller pressure, sample introduction tubing, correct pump rotation, and condition of drain tubing.	Clean all filters and fans.	Replace oil in roughing pumps.	Replace oil in turbo-molecular pump.	Check electronic settings for optimum sensitivity: resolution, mass calibration, ion optics, CEM, deflector voltage.
Check quartz torch condition.	Check condition of sampler and skimmer cones.	Check recirculator water level.			
Measure quartz torch for proper alignment.	Check and drain oil mist eliminator on roughing pumps.				
Clean spray chamber and nebulizer.					
Check oil level of roughing pumps.					

SECTION 21

MEASUREMENT TRACEABILITY

21.1 Overview

Traceability of measurements shall be assured using a system of documentation, calibration, and analysis of reference standards. Laboratory equipment that are peripheral to analysis and whose calibration is not necessarily documented in a test method analysis or by analysis of a reference standard shall be subject to ongoing certifications of accuracy. At a minimum, these must include procedures for checking specifications of ancillary equipment: balances, thermometers, temperature, Deionized (DI) and Reverse Osmosis (RO) water systems, automatic pipettes and other volumetric measuring devices. (Refer to Section 20.3). With the exception of Class A Glassware and Glass microliter syringes, quarterly accuracy checks are performed for all mechanical volumetric devices. Microsyringes can be verified at least semi-annually or disposed of after 6 months of use. Wherever possible, subsidiary or peripheral equipment is checked against standard equipment or standards that are traceable to national or international standards. Class A Glassware and Glass microliter syringes should be routinely inspected for chips, acid etching or deformity (e.g., bent needle). If the Class A glassware or syringe is suspect, the accuracy of the glassware will be assessed prior to use.

21.2 NIST-Traceable Weights And Thermometers

Reference standards of measurement shall be used for calibration only and for no other purpose, unless it can be shown that their performance as reference standards would not be invalidated.
For NIST-traceable weights and thermometers, the laboratory requires that all calibrations be conducted by a calibration laboratory accredited by A2LA, NVLAP (National Voluntary Laboratory Accreditation Program) or another accreditation organization that is a signatory to a MRA (Mutual Recognition Arrangement) of one or more of the following cooperations – ILAC (International Laboratory Accreditation Cooperation) or APLAC (Asia – Pacific Laboratory Accreditation Cooperation). A certificate and scope of accreditation is kept on file at the laboratory.

Additional details can be found in laboratory SOP No's. PT-QA-008 and PT-QA-012.

21.3 Reference Standards / Materials

Reference standards/materials, where commercially available, are traceable to certified reference materials. Commercially prepared reference standards, to the extent available, are purchased from vendors accredited to ISO Guide 34 and ISO/IEC Guide 17025. All reference standards from commercial vendors shall be accompanied by a certificate that includes at least the following information:

- Manufacturer
- Analytes or parameters calibrated
- Identification or lot number
- Calibration method
- Concentration with associated uncertainties
- Purity

If a standard cannot be purchased from a vendor that supplies a Certificate of Analysis, the purity of the standard is documented by analysis. The receipt of all reference standards must be documented in the LIMS. Reference standards are labeled with a unique Standard Identification Number and expiration date. All documentation received with the reference standard is retained as a QC record and references the Standard Identification Number.

All reference, primary and working standards/materials, whether commercially purchased or laboratory prepared, must be checked regularly to ensure that the variability of the standard or material from the true value does not exceed method requirements. The accuracy of calibration standards is checked by comparison with a standard from a second source. In cases where a second standard manufacturer is not available, a vendor certified different lot is acceptable for use as a second source. For unique situations, such as air analysis where no other source or lot is available, a standard made by a different analyst would be considered a second source. The appropriate Quality Control (QC) criteria for specific standards are defined in laboratory SOPs. In most cases, the analysis of an Initial Calibration Verification (ICV) or LCS (where there is no sample preparation) is used as the second source confirmation. These checks are generally performed as an integral part of the analysis method (e.g. calibration checks, laboratory control samples).

All standards and materials must be stored and handled according to method or manufacturer's requirements in order to prevent contamination or deterioration. Refer to the Corporate Environmental Health & Safety Manual or laboratory SOPs. For safety requirements, please refer to method SOPs and the laboratory Environmental Health and Safety Manual.

Standards and reference materials shall not be used after their expiration dates unless their reliability is verified by the laboratory and their use is approved by the Quality Assurance Manager. The laboratory has contingency procedures for re-verifying expired standards. See Pittsburgh Laboratory SOP No. PT-QA-006, *Procurement of Standards and Materials, Labeling and Traceability*.

21.4 Documentation And Labeling Of Standards, Reagents, And Reference Materials

Reagents must be at a minimum the purity required in the test method. The date of reagent receipt and the expiration date are documented. The lots for most of the common solvents and acids are tested for acceptability prior to company-wide purchase. (Refer to Eurofins TestAmerica's Corporate SOP No. CA-Q-S-001, *Acid & Solvent Lot Testing and Approval*.)

All manufacturer or vendor supplied Certificate of Analysis or Purity must be retained, stored appropriately, and readily available for use and inspection. These records are maintained in the QA public drive and in the LIMS, scanned into Reagent log. Records must be kept of the date of receipt and date of expiration of standards, reagents and reference materials. In addition, records of preparation of laboratory standards, reagents, and reference materials must be retained, stored appropriately, and be readily available for use and inspection. For detailed information on documentation and labeling, please refer to laboratory analytical SOPs and SOP PT-QA-006.

Commercial materials purchased for preparation of calibration solutions, spike solutions, etc., are usually accompanied with an assay certificate or the purity is noted on the label. If the assay

purity is 96% or better, the weight provided by the vendor may be used without correction. If the assay purity is less than 96% a correction will be made to concentrations applied to solutions prepared from the stock commercial material.

21.4.1 All standards, reagents, and reference materials that may affect quality must be labeled in an unambiguous manner. Standards are logged into TALS, and are assigned a unique identification number. The following information is typically recorded within TALS.

- Standard ID
- Description of Standard
- Department
- Preparer's name
- Final volume and number of vials prepared
- Solvent type and lot number
- Preparation Date or Date opened
- Expiration Date
- Standard source type (stock or daughter)
- Standard type (spike, surrogate, other)
- Parent standard ID (if applicable)
- Parent Standard Analyte Concentration (if applicable)
- Parent Standard Amount used (if applicable)
- Component Analytes
- Final concentration of each analyte
- Comment box (text field)

Records are maintained electronically for standard and reference material preparation. These records show the traceability to purchased stocks or neat compounds. These records also include method of preparation, date of preparation, expiration date and preparer's name or initials. Preparation procedures are provided in the laboratory analytical SOPs.

21.4.2 All standards, reagents, and reference materials must be clearly labeled with a minimum of the following information:

- Date prepared or Date opened
- Expiration Date (include prep date for reagents)
- Standard ID (from electronic standard log in TALS)
- Special Health/Safety warnings if applicable

Records must also be maintained of the date of receipt for commercially purchased items or date of preparation for laboratory prepared items. Special Health/Safety warnings must also be available to the analyst. This information is maintained in standard/reagent log. Health and safety warning are in the SDS (Safety Data Sheets) which is accessed through the company intranet site.

21.4.3 In addition, the following information may be included:

- Description of standard (if different from manufacturer's label or if standard was prepared in the laboratory)
- Recommended Storage Conditions
- Concentration (if applicable)
- Initials of analyst preparing standard or opening container

All containers of prepared reagents must include, expiration date and an ID number to trace back to preparation.

Procedures for preparation of reagents can be found in the Method SOPs.

Standard ID numbers must be traceable through associated logbooks, worksheets and raw data.

All reagents and standards must be stored in accordance to the following priority: 1) with the manufacturer's recommendations; 2) with requirements in the specific analytical methods as specified in the laboratory SOP.

SECTION 22

SAMPLING

22.1 Overview

The laboratory provides sampling services for the following matrices:

- Groundwater
- Wastewater
- Potable Water
- Wastes
- Soil and Sediment

The laboratory also offers the following services:

- Flow Monitoring
- Field Parameter Analysis

Field Analyses are address in Eurofins TestAmerica Pittsburgh SOP No.'s:

- PT-FS-001 – Field Measurement of Dissolved Oxygen (DO)
- PT-FS-002 – Field Measurement of Total Residual Chlorine
- PT-FS-003 – Field Measurement of pH
- PT-FS-004 – General Sampling

22.2 Sampling Containers

The laboratory offers clean sampling containers for use by clients. These containers are obtained from reputable container manufacturers and meet EPA specifications as required. Certificates of cleanliness for bottles and preservatives are provided by the supplier and are

maintained at the laboratory. Alternatively, the certificates may be maintained by the supplier and available to the laboratory on-line.
For detailed information regarding container/bottle order, refer to laboratory SOP No. PT-SR-002, *Bottle Order Preparation and Shipping*.

22.2.1 Preservatives

Upon request, preservatives are provided to the client in pre-cleaned sampling containers. In general, containers are purchased pre-preserved from the container supplier. Whether prepared by the laboratory or bought pre-preserved, the grades of the preservatives are at a minimum:

- Hydrochloric Acid – AR Select (ACS) or equivalent
- Methanol – Purge and Trap grade
- Nitric Acid – AR Select (ACS), Trace-Metals Grade or equivalent
- Sodium Hydroxide – AR Select (ACS) or equivalent
- Sulfuric Acid – AR Select (ACS) or equivalent
- Sodium Thiosulfate – ACS Grade or equivalent
- Sodium Bisulfate – ACS Grade or equivalent

22.3 Definition Of Holding Time

The date and time of sampling documented on the COC form establishes the day and time zero. As a general rule, when the maximum allowable holding time is expressed in days (e.g., 14 days, 28 days), the holding time is based on calendar day measured. Holding times expressed in hours (e.g., 6 hours, 24 hours, etc.) are measured from date and time zero. However, there are some programs that determine holding time compliance based on the date and specific time of analysis compared to the time of sampling regardless of how long the holding time is. Holding times for analysis include any necessary reanalysis.

22.4 Sampling Containers, Preservation Requirements, Holding Times

The container type, preservation, and holding time criteria specified in the SOPs are derived from the source documents for the methods. If method required holding times as specified in the SOPs or preservation requirements are not met, the reports will be qualified using a flag, footnote or case narrative. As soon as possible, or “ASAP”, is an EPA designation for tests for which rapid analysis is advised, but for which neither EPA nor the laboratory have a basis for a holding time.

22.5 Sample Aliquots / Subsampling

Taking a representative sub-sample from a container is necessary to ensure that the analytical results are representative of the sample collected in the field. The size of the sample container, the quantity of sample fitted within the container, and the homogeneity of the sample need consideration when sub-sampling for sample preparation. It is the laboratory’s responsibility to take a representative subsample or aliquot of the sample provided for analysis.

Analysts should handle each sample as if it is potentially dangerous. At a minimum, safety glasses, gloves, and lab coats must be worn when preparing aliquots for analysis.

Guidelines for subsampling are located in laboratory SOP PT-QA-024.

SECTION 23

HANDLING OF SAMPLES

Sample management procedures at the laboratory ensure that sample integrity and custody are maintained and documented from sampling/receipt through disposal. Details can be found in laboratory SOP No. PT-SR-001, *Sample Receipt and Login*, and PT-HS-001, *Pittsburgh Facility Addendum EH&S Manual*.

23.1 Chain Of Custody (COC)

The COC form is the written documented history of any sample and is initiated when bottles are sent to the field, or at the time of sampling. This form is completed by the sampling personnel and accompanies the samples to the laboratory where it is received and stored under the laboratory's custody. The purpose of the COC form is to provide a legal written record of the handling of samples from the time of collection until they are received at the laboratory. It also serves as the primary written request for analyses from the client to the laboratory. The COC form acts as a purchase order for analytical services when no other contractual agreement is in effect. An example of a COC form may be found in Figure 23-1.

23.1.1 Field Documentation

The information the sampler needs to provide at the time of sampling on the container label is:

- Sample identification
- Date and time
- Preservative

During the sampling process, the COC form is completed and must be legible (see Figure 23-1). This form includes information such as:

- Client name, address, phone number and fax number (if available)
- Project name and/or number
- The sample identification
- Date, time and location of sampling
- Sample collectors name
- The matrix description
- The container description
- The total number of each type of container
- Preservatives used
- Analysis requested
- Requested turnaround time (TAT)
- Any special instructions
- Purchase Order number or billing information (e.g. quote number) if available
- The date and time that each person received or relinquished the sample(s), including their signed name.

When the sampling personnel deliver the samples directly to Eurofins TestAmerica personnel, the samples are stored in a cooler with ice, as applicable, and remain solely in the possession of the client's field technician until the samples are delivered to the laboratory personnel. The sample collector must assure that each container is in his/her physical possession or in his/her view at all times, or stored in such a place and manner to preclude tampering. The field technician relinquishes the samples in writing on the COC form to the sample control personnel at the laboratory or to a Eurofins TestAmerica courier. When sampling personnel deliver the samples through a common carrier (Fed-Ex, UPS), the CoC relinquished date/time is completed by the field personnel and samples are released to the carrier. Samples are only considered to be received by laboratory when personnel at the fixed laboratory facility have physical contact with the samples.

Note: Independent couriers are not required to sign the COC form. The COC is usually kept in the sealed sample cooler. The receipt from the courier is stored in login by date; it lists all receipts for each date.

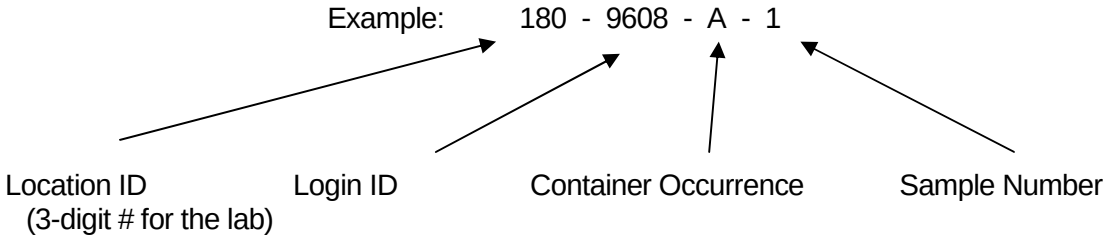
23.1.2 Legal / Evidentiary Chain-of-Custody

If samples are identified for legal/evidentiary purposes on the COC, login will complete the custody seal retain the shipping record with the COC, and initiate an internal COC for laboratory use by analysts and a sample disposal record.

23.2 Sample Receipt

Samples are received at the laboratory by designated sample receiving personnel and a unique laboratory project identification number is assigned. Each sample container shall be assigned a unique sample identification number that is cross-referenced to the client identification number such that traceability of test samples is unambiguous and documented. Each sample container is affixed with a durable sample identification label. Sample acceptance, receipt, tracking and storage procedures are summarized in the following sections.

23.2.1 Laboratory Receipt



When samples arrive at the laboratory, sample receiving personnel inspect the coolers and samples. The integrity of each sample must be determined by comparing sample labels or tags with the COC and by visual checks of the container for possible damage. Samples and COC must meet the laboratory Sample Acceptance Policy (Figure 23-2). Any non-conformance, irregularity, or compromised sample receipt must be documented in TALS on the Sample Receipt checklist (Figure 23-3), and must be brought to the immediate attention of the client. The COC, shipping documents, documentation of any non-conformance, irregularity, or compromised sample receipt, record of client contact, and resulting instructions become part of the project record. This procedure is further described in laboratory SOP PT-SR-01.

23.2.1.1 Unique Sample Identification

All samples that are processed through the laboratory receive a unique sample identification to ensure that there can be no confusion regarding the identity of such samples at anytime. This

system includes identification for all samples, subsamples and subsequent extracts and/or digestates.

The laboratory assigns a unique identification (e.g., Sample ID) code to each sample container received at the laboratory. This Primary ID is made up of the following information (consisting of 4 components):

The above example states that Eurofins TestAmerica Pittsburgh Laboratory (Location 180). Login ID is 9608 (unique to a particular client/job occurrence). The container code indicates it is the first container ("A") of Sample #1.

If the primary container goes through a prep step that creates a "new" container, then the new container is considered secondary and gets another ID. An example of this being a client sample in a 1-Liter amber bottle is sent through a Liquid/Liquid Extraction and an extraction vial is created from this step. The vial would be a SECONDARY container. The secondary ID has 5 components.

Example: 180 - 9608 - A - 1 - **A** ←——**Secondary Container Occurrence**

Example: 180-9608-A-1-A, would indicate the PRIMARY container listed above that went through a step that created the 1st occurrence of a Secondary container.

With this system, a client sample can literally be tracked throughout the laboratory in every step from receipt to disposal.

23.3 Sample Acceptance Policy

The laboratory has a written sample acceptance policy (Figure 23-2) that clearly outlines the circumstances under which samples shall be accepted or rejected. These include:

- a COC must filled out completely
- samples must be properly labeled
- proper sample containers with adequate volume for the analysis and necessary QC
- samples must be preserved according to the requirements of the requested analytical method
- sample holding times must be adhered to
- Samples that require chilling must be received proper temperature
- the project manager will be notified if any sample is received in damaged condition

Data from samples which do not meet these criteria are flagged and the nature of the variation from policy is defined.

23.3.1.1 After inspecting the samples, the sample receiving personnel sign and date the COC form, make any necessary notes of the samples' conditions and store them in appropriate refrigerators or storage locations.

23.3.1.2 Any deviations from these checks that question the suitability of the sample for analysis, or incomplete documentation on the chain-of-custody will be resolved by consultation with the client. If the sample acceptance policy criteria are not met, the laboratory shall either:

- Retain all correspondence and/or records of communications with the client regarding the disposition of rejected samples, or
- Fully document any decision to proceed with sample analysis that does not meet sample acceptance criteria. Include information for the case narrative of the report.
- If the conditions listed on the Acceptance Policy are not satisfactory and when lacking direction or agreement with the client, the sample may be rejected by the laboratory.
- Any deviation that impacts sample results, such as temperature and preservation, shall be noted on sample results.

Note: North Carolina requires that they be notified when samples are processed that do not meet sample acceptance criteria.

Once sample acceptance is verified, the samples are logged into the TALS according to laboratory SOP PT-SR-001.

23.4 Sample Storage

In order to avoid deterioration, contamination or damage to a sample during storage and handling, from the time of receipt until all analyses are complete, samples are stored in refrigerators, freezers, or protected locations suitable for the sample matrix. In addition, samples to be analyzed for volatile organic parameters are stored in separate refrigerators designated for volatile organic parameters only. Samples are never to be stored with reagents, standards or materials that may create contamination.

To ensure the integrity of the samples during storage, refrigerator blanks are maintained in the volatile sample refrigerators and analyzed at least every two weeks. See laboratory SOP PT-MS-005, *Volatile Holding Blanks*.

Analysts and technicians retrieve the sample container allocated to their analysis from the designated storage location and place them on carts, analyze the sample, and return the remaining sample or empty container to the storage location from which it originally came. All unused portions of samples, including empty sample containers, are returned to the secure sample control area. Raw samples requiring cold storage are kept in the cold room for approximately 30 days after reported. Volatile samples are stored in the VOA refrigerator. All sample extracts are kept in the refrigerators for approximately two to four weeks after analysis,

which meets or exceeds most sample holding times. After the cold storage time, the samples are moved to dry room-temperature sample archive area, where they are stored for an additional four weeks before they are disposed of. This holding period allows samples to be checked if a discrepancy or question arises. Special arrangements may be made to store samples for longer periods of time. This extended holding period allows additional metal analyses to be performed on the archived sample and assists clients in dealing with legal matters or regulatory issues.

Access to the laboratory is controlled such that sample storage need not be locked at all times unless a project specifically demands it. Samples are accessible to laboratory personnel only. Visitors to the laboratory are prohibited from entering the refrigerator and laboratory areas unless accompanied by an employee of Eurofins TestAmerica.

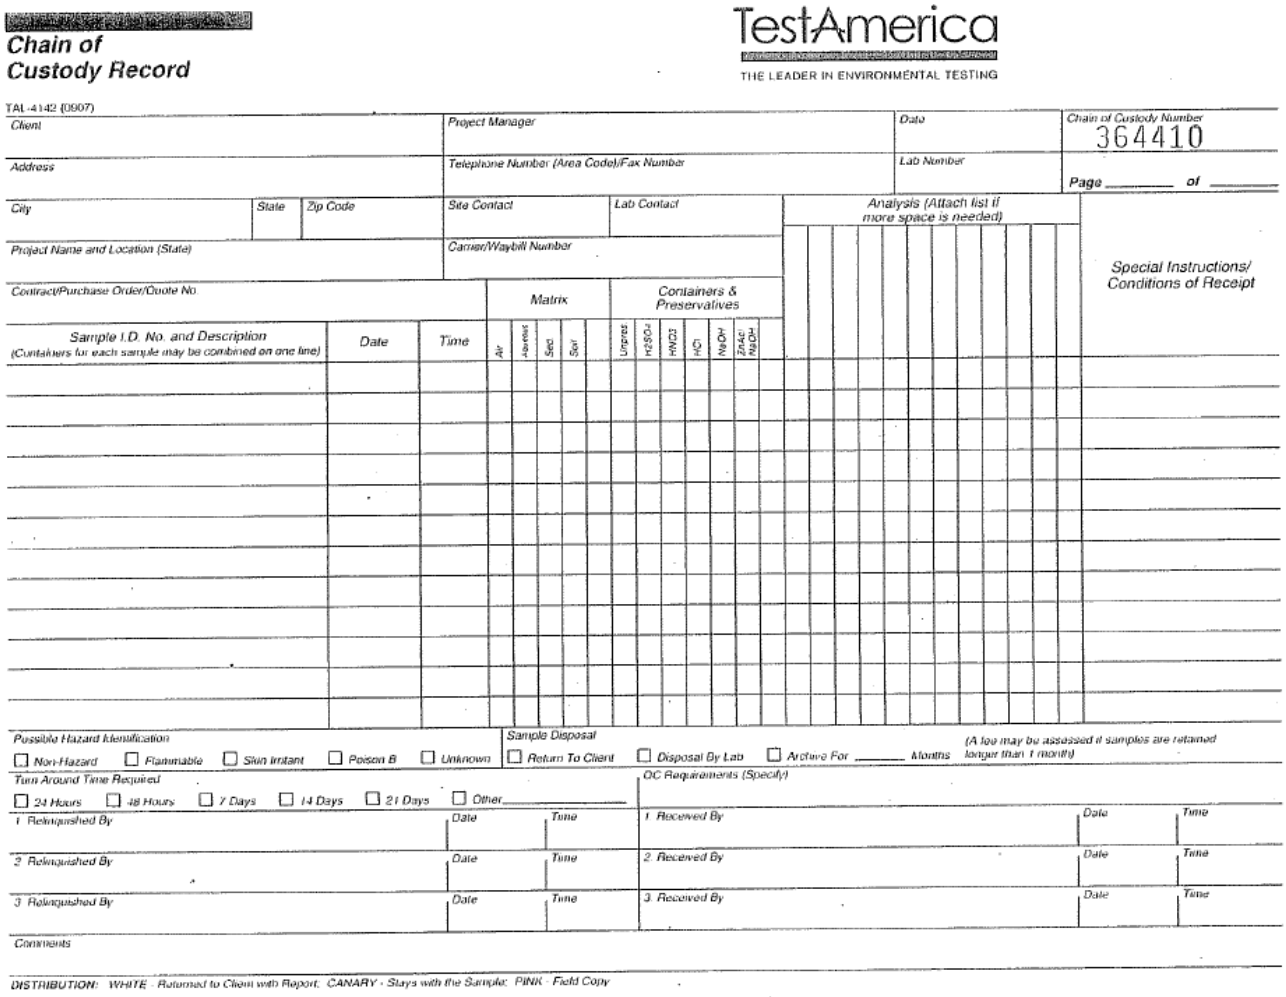
23.5 Hazardous Samples And Foreign Soils

To minimize exposure to personnel and to avoid potential accidents, hazardous, for any sample that is known to be hazardous at the time of receipt a cautionary email communication should be sent to all applicable laboratory personnel by the project manager or designee. All hazardous samples are disposed of appropriately through a hazardous waste disposal process. Foreign soil samples are sent out for incineration by an USDA-approved waste disposal facility. Analysts will notify Sample Control of any sample determined to be hazardous after completion of analysis by sending an email. All hazardous samples are either returned to the client or disposed of appropriately through a hazardous waste disposal firm that lab-packs all hazardous samples and removes them from the laboratory. Foreign soil samples are sent out for incineration by a USDA-approved waste disposal facility.

23.6 Sample Shipping

In the event that the laboratory needs to ship samples, the samples are placed in a cooler with enough ice to ensure the samples remain just above freezing and at or below 6.0°C during transit. The samples are carefully surrounded by packing material to avoid breakage (yet maintain appropriate temperature). A trip blank is enclosed for those samples requiring water/solid volatile organic analyses. The chain-of-custody form is signed by the sample control technician and attached to the shipping paperwork. Samples are generally shipped overnight express or hand-delivered by a Eurofins TestAmerica courier to maintain sample integrity. All personnel involved with shipping and receiving samples must be trained to maintain the proper chain-of-custody documentation and to keep the samples intact and on ice. The Environmental, Health and Safety Manual contains additional shipping requirements.

Note: If a client does not request trip blank analysis on the COC or other paperwork, the laboratory will not analyze the trip blanks that were supplied. However, in the interest of good client service, the laboratory will advise the client at the time of sample receipt that it was noted that they did not request analysis of the trip blank; and that the laboratory is providing the notification to verify that they are not inadvertently omitting a key part of regulatory compliance testing.



23.7 Sample Disposal

Samples should be retained for a minimum of 30 days after the project report is sent, however, provisions may be made for earlier disposal of samples once the holding time is exceeded. Some samples are required to be held for longer periods based on regulatory or client requirements (e.g., 60 days after project report is sent). The laboratory must follow the longer sample retention requirements where required by regulation or client agreement. Several possibilities for sample disposal exist: the sample may be consumed completely during analysis, the sample may be returned to the customer or location of sampling for disposal, or the sample may be disposed of in accordance with the laboratory's waste disposal procedures (SOP No. PT-HS-001). All procedures in the laboratory Environmental, Health and Safety Manual are followed during disposal. Samples are normally maintained in the laboratory no longer than two months from receipt unless otherwise requested. Unused portions of samples found or suspected to be hazardous according to state or federal guidelines may be returned to the client upon completion of the analytical work.

If a sample is part of a known litigation, the affected legal authority, sample data user, and/or submitter of the sample must participate in the decision about the sample's disposal. All documentation and correspondence concerning the disposal decision process must be kept on file. Pertinent information includes the date of disposal, nature of disposal (such as sample depletion, hazardous waste facility disposal, return to client), names of individuals who conducted the arrangements and physically completed the task. The laboratory will remove or deface sample labels prior to disposal unless this is accomplished through the disposal method (e.g., samples are incinerated). A Waste Disposal Record should be completed.

Figure 23-1

Comments

DISTRIBUTION: WHITE - Returned to Client with Report; CANARY - Stays with the Sample; PINK - Field Copy

Figure 23-2

Sample Acceptance Policy

All incoming work will be evaluated against the criteria listed below. Where applicable, data from any samples that do not meet the criteria listed below will be noted on the laboratory report defining the nature and substance of the variation. In addition the client will be notified either by telephone, fax or e-mail ASAP after the receipt of the samples.

1) Samples must arrive with labels intact with a Chain of Custody filled out completely. The following information must be recorded.
   - *Client name, address, phone number and fax number (if available)*
   - *Project name and/or number*
   - *Unique sample identification*
   - *Date, time and location of sampling*
   - *The collectors name*
   - *The matrix description*
   - *The container description*
   - *The total number of each type of container*
   - *Preservatives used*
   - *Analysis requested*
   - *Requested turnaround time (TAT)*
   - *Any special instructions*
   - *Purchase Order number or billing information (e.g. quote number) if available*
   - *The date and time that each person received or relinquished the sample(s), including their signed name.*
   - **Information must be legible**

2) Samples must be properly labeled.
   - Use durable labels (labels provided by Eurofins TestAmerica are preferred)
   - Include a unique identification number
   - Include sampling date and time & sampler ID
   - Include preservative used.
   - Use indelible ink
   - **Information must be legible**

3) Proper sample containers with adequate volume for the analysis and necessary QC are required for each analysis requested.

4) Samples must be preserved according to the requirements of the requested analytical method. (See Sampling Guide)

5) Most analytical methods require chilling samples to 4^{o} C (other than water samples for metals analysis). For these methods, the criteria are met if the samples are chilled to below 6^{o} C and above freezing (0^{o}C). For methods with other temperature criteria (e.g. some bacteriological methods require $\leq$ 10 ^{o}C), the samples must arrive within $\pm$ 2^{o} C of the required temperature or within the method specified range. **Note:** Samples that are hand delivered to the laboratory immediately after

collection may not have had time to cool sufficiently. In this case the samples will be considered acceptable as long as there is evidence that the chilling process has begun (arrival on ice).

5i.) Samples that are delivered to the laboratory on the same day they are collected may not meet the requirements of Section 5. In these cases, the samples shall be considered acceptable if the samples were received on ice.

5ii.) If sample analysis is begun within fifteen (15) minutes of collection, thermal preservation is not required.

5iii.) Thermal preservation is not required in the field if the laboratory receives and refrigerates the sample within fifteen (15) minutes of collection.

- Chemical preservation (pH) will be verified prior to analysis and documented, either in sample control or at the analyst's level. The project manager will be notified immediately if there is a discrepancy. If analyses will still be performed, all affected results will be flagged to indicate improper preservation.

- **FOR WATER SAMPLES TESTED FOR AVAILABLE / FREE CYANIDE (Method OIA-1677)**
  - In the Field: Samples will be collected in pre-preserved bottles for both a regular sample collection and a 1:10 diluted sample in case of the presence of sulfide.
    - The lab will test the samples for sulfide using lead acetate paper at the time of analysis and if sulfide is present in the sample above 50mg/L, the diluted sample will be analyzed.
    - If the water being collected may contain residual chlorine or other oxidizer, the sample should be treated at time of collection with sodium arsenite.

- Water samples that require ortho-phosphorus must be filtered in the field within 15 minutes of sampling. Samples received without indication of filtration in the field will have results flagged for improper preservation.

- Water samples being collected for dissolved metals analysis should be filtered in the field within 15 minutes of sampling and prior to preservation.

- Samples for coliform analysis must be in sterile containers and must be free of residual chlorine. The bottle must be filled to <u>above</u> the 100mL mark.

6) For the laboratory to meet method requirements for the analysis of *Duplicate, Matrix Spikes* and/ or *Matrix Spike Duplicates*, extra volume for at least 1 samples should be collected.
   - If *Matrix Spikes* are required on a specific sample for your project, separate sample volumes for the required QC must be collected for the requested analyses.

7) For Volatile Organic analyses: Efforts should be made to minimize any air bubbles in aqueous volatile samples. Air bubbles also the escape of volatile organics. This is especially important because air bubbles tend to form in iced samples. Volatile vials containing air bubbles larger than a pea will be treated as non-conformances.

8) All samples submitted for Volatile Organic analyses, including by method 8011, must have a Trip Blank submitted at the same time. Eurofins TestAmerica will supply a blank with the bottle order.

9) Sample Holding Times

   - Eurofins TestAmerica will make every effort to analyze samples within the regulatory holding time. Samples must be received in the laboratory with enough time to perform the sample

analysis. Except for short holding time samples (< 48hr HT) sample must be received with at least 48 hrs (working days) remaining on the holding time for us to ensure analysis.

- Analyses that are designated as "field" analyses (Odor, pH, Dissolved Oxygen, Disinfectant Residual; a.k.a. Residual Chlorine, and Redox Potential) should be analyzed ASAP by the field sampler prior to delivering to the lab (within 15 minutes). However, if the analyses are to be performed in the laboratory, Eurofins TestAmerica will make every effort to analyze the samples within 24 hours from receipt of the samples in the testing laboratory. Samples for "field" analyses received after 4:00 pm on Friday or on the weekend will be analyzed no later than the next business day after receipt (Monday unless a holiday). Samples will remain refrigerated and sealed until the time of analysis. Samples analyzed in the laboratory will be qualified on the final report to indicate holding time exceedance.

10) The project manager will be notified if any sample is received in damaged condition. Eurofins TestAmerica will request that a sample be resubmitted for analysis. The laboratory will notify the client upon sample receipt if the samples exhibit obvious signs of damage, contamination or inadequate preservation.

11) Recommendations for packing samples for shipment.

- Pack samples in Ice rather than "Blue" ice packs.

- Soil samples should be placed in plastic zip-lock bags. The containers often have dirt around the top and do not seal very well and are prone to intrusion from the water from melted ice.

- Water samples would be best if wrapped with bubble-wrap or paper (newspaper, or paper towels work) and then placed in plastic zip-lock bags.

- Fill extra cooler space with bubble wrap.

12) If the conditions listed on the Acceptance Policy are not satisfactory and when lacking direction or agreement with the client, the sample will be rejected by the laboratory.

Question	Answer	Comment
Radioactivity either was not measured or, if measured, is at or below background	True	
The cooler's custody seal, if present, is intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the sample IDs on the containers and the COC.	True	
Samples are received within Holding Time.	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
VOA sample vials do not have headspace or bubble is <6mm (1/4") in diameter.	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A	

SECTION 24

ASSURING THE QUALITY OF TEST RESULTS

24.1 Overview

In order to assure our clients of the validity of their data, the laboratory continuously evaluates the quality of the analytical process. The analytical process is controlled not only by instrument calibration as discussed in Section 20, but also by routine process quality control measurements (e.g. Blanks, Laboratory Control Samples (LCS), Matrix Spikes (MS), duplicates (DUP), surrogates, Internal Standards (IS)). These quality control checks are performed as required by the method or regulations to assess precision and accuracy. Quality control samples are to be treated in the exact same manner as the associated field samples being tested. In addition to the routine process quality control samples, Proficiency Testing (PT) Samples (concentrations unknown to laboratory) are analyzed to help ensure laboratory performance.

24.2 Controls

Sample preparation or pre-treatment is commonly required before analysis. Typical preparation steps include homogenization, solvent extraction, sonication, acid digestion, filtration, distillation, reflux, evaporation, drying and ashing. During these pre-treatment steps, samples are arranged into discreet manageable groups referred to as preparation (prep) batches. Prep batches provide a means to control variability in sample treatment. Control samples are added to each prep batch to monitor method performance and are processed through the entire analytical procedure with investigative/field samples.

24.3 Negative Controls

Table 24-1. Negative Controls

Control Type	Details
Method Blank (MB)	are used to assess preparation and analysis for possible contamination during the preparation and processing steps.
	The specific frequency of use for method blanks during the analytical sequence is defined in the specific standard operating procedure for each analysis. Generally it is 1 for each batch of samples; not to exceed 20 environmental samples.
	The method blank is prepared from a clean matrix similar to that of the associated samples that is free from target analytes (e.g., Reagent water, Ottawa sand, glass beads, etc.) and is processed along with and under the same conditions as the associated samples. The method blank goes through all of the steps of the process (including as necessary: filtration, clean-ups, etc.).
	Reanalyze or qualify associated sample results when the concentration of a targeted analyte in the blank is at or above the reporting limit as established by the method or by regulation, AND is greater than 1/10 of the amount measured in the sample.
Calibration Blanks	are prepared and analyzed along with calibration standards where applicable. They are prepared using the same reagents that are used to prepare the standards. In some analyses the calibration blank may be included in the calibration curve.

Table 24-1. Negative Controls

Control Type	Details
Instrument Blanks	are blank reagents or reagent water that may be processed during an analytical sequence in order to assess contamination in the analytical system. In general, instrument blanks are used to differentiate between contamination caused by the analytical system and that caused by the sample handling or sample prep process. Instrument blanks may also be inserted throughout the analytical sequence to minimize the effect of carryover from samples with high analyte content.
Trip Blank [1]	are required to be submitted by the client with each shipment of samples requiring aqueous and solid volatiles analyses (or as specified in the client's project plan). Additionally, trip blanks may be prepared and analyzed for volatile analysis of air samples, when required by the client. A trip blank may be purchased (certified clean) or is prepared by the laboratory by filling a clean container with pure deionized water that has been purged to remove any volatile compounds. Appropriate preservatives are also added to the container. The trip blank is sent with the bottle order and is intended to reflect the environment that the containers are subjected to throughout shipping and handling and help identify possible sources if contamination is found. The field sampler returns the trip blank in the cooler with the field samples.
Field Blanks [1]	are sometimes used for specific projects by the field samplers. A field blank prepared in the field by filling a clean container with pure reagent water and appropriate preservative, if any, for the specific sampling activity being undertaken. (EPA OSWER)
Equipment Blanks [1]	are also sometimes created in the field for specific projects. An equipment blank is a sample of analyte-free media which has been used to rinse common sampling equipment to check effectiveness of decontamination procedures. (TNI)
Holding Blanks	also referred to as refrigerator or freezer blanks, are used to monitor the sample storage units for volatile organic compounds during the storage of VOA samples in the laboratory

[1] When known, these field QC samples should not be selected for matrix QC as it does not provide information on the behavior of the target compounds in the field samples. Usually, the client sample ID will provide information to identify the field blanks with labels such as "FB", "EB", or "TB."

Evaluation criteria and corrective action for these controls are defined in the specific standard operating procedure for each analysis. Also further detail is provided in SOP No. PT-QA-021.

24.3.1 Negative Controls for Microbiological Methods – Microbiological Methods utilize a variety of negative controls throughout the process to ensure that false positive results are not obtained. These controls are critical to the validity of the microbiological analyses. Some of these negative controls are:

Table 24-2. Negative Controls for Microbiology

Control Type	Details
Sterility Checks (Media)	are analyzed for each lot of pre-prepared media, ready-to-use media and for each batch of medium prepared by the laboratory.
Filtration Blanks	blanks are run at the beginning and end for each sterilized filtration unit used in a filtration series. For pre-sterilized single use funnels a sterility check is performed on at least one funnel per lot.
Sterility checks (Sample Containers)	are performed on at least one container per lot of purchased, pre-sterilized containers. If containers are prepared and sterilized by the laboratory, one container per sterilization batch is checked. Container sterility checks are performed using non-selective growth media.

Sterility Checks (Dilution Water)	are performed on each batch of dilution water prepared by the laboratory and on each batch of pre-prepared dilution water. All checks are performed using non-selective growth media.
Sterility Checks (Filters)	are also performed on at least one filter from each new lot of membrane filters using non-selective growth media.

Negative culture controls demonstrate that a media does not support the growth of non-target organisms and ensures that there is not an atypical positive reaction from the target organisms. Prior to the first use of the media, each lot of pre-prepared selective media or batch of laboratory prepared selective media is analyzed with at least one known negative culture control as appropriate to the method.

24.4 Positive Controls

Control samples (e.g., QC indicators) are analyzed with each batch of samples to evaluate data based upon (1) Method Performance (Laboratory Control Sample (LCS) or Blank Spike (BS)), which entails both the preparation and measurement steps; and (2) Matrix Effects (Matrix Spike (MS) or Sample Duplicate (MD, DUP), which evaluates field sampling accuracy, precision, representativeness, interferences, and the effect of the matrix on the method performed. Each regulatory program and each method within those programs specify the control samples that are prepared and/or analyzed with a specific batch

Note that frequency of control samples vary with specific regulatory, methodology and project specific criteria. Complete details on method control samples are as listed in each analytical SOP.

24.4.1 Method Performance Control - Laboratory Control Sample (LCS)

The LCS measures the accuracy of the method in a blank matrix and assesses method performance independent of potential field sample matrix affects in a laboratory batch.

The LCS is prepared from a clean matrix similar to that of the associated samples that is free from target analytes (for example: Reagent water, Ottawa sand, glass beads, etc.) and is processed along with and under the same conditions as the associated samples. The LCS is spiked with verified known amounts of analytes or is made of a material containing known and verified amounts of analytes, taken through all preparation and analysis steps along with the field samples. Where there is no preparation taken for an analysis (such as in aqueous volatiles), or when all samples and standards undergo the same preparation and analysis process (such as Phosphorus), a calibration verification standard may be reported as the LCS. In some instances where there is no practical clean solid matrix available, aqueous LCS's may be processed for solid matrices; final results may be calculated as mg/kg or ug/kg, assuming 100% solids and a weight equivalent to the aliquot used for the corresponding field samples, to facilitate comparison with the field samples.

Certified pre-made reference material purchased from a NIST/A2LA accredited vendor may also be used for the LCS when the material represents the sample matrix or the analyte is not easily spiked (e.g. solid matrix LCS for metals, TDS, etc.).

The specific frequency of use for LCS during the analytical sequence is defined in the specific standard operating procedure for each analysis. It is generally 1 for each batch of samples; not to exceed 20 environmental samples.

If the mandated or requested test method, or project requirements, do not specify the spiking components, the laboratory shall spike all reportable components to be reported in the Laboratory Control Sample (and Matrix Spike) where applicable (e.g. no spike of pH). However, in cases where the components interfere with accurate assessment (such as simultaneously spiking chlordane, toxaphene and PCBs in Method 608), the test method has an extremely long list of components or components are incompatible, at a minimum, a representative number of the listed components (see below) shall be used to control the test method. The selected components of each spiking mix shall represent all chemistries, elution patterns and masses, permit specified analytes and other client requested components. However, the laboratory shall ensure that all reported components are used in the spike mixture within a two-year time period.

- For methods that have 1-10 target analytes, spike all components.
- For methods that include 11-20 target analytes, spike at least 10 or 80%, whichever is greater.
- For methods with more than 20 target analytes, spike at least 16 components.
- Exception: Due to analyte incompatibility in pesticides, Toxaphene and Chlordane are only spiked at client request based on specific project needs.
- Exception: Due to analyte incompatibility between the various PCB aroclors, aroclors 1016 and 1260 are used for spiking as they cover the range of all of the aroclors. Specific aroclors may be used by request on a project specific basis.

24.4.2 Positive Controls for Microbiological Methods

- Each lot of pre-prepared media (including chromofluorogenic reagent) and each batch of laboratory prepared media is tested with a pure culture of known positive reaction.

- In addition, every analytical batch also contains a pure culture of known positive reaction.

  A pure culture of known negative reaction is also tested with each analytical batch to ensure specificity of the procedure.

24.5 Sample Matrix Controls

Table 24-3 Sample Matrix Control

Control Type	Details	
Matrix Spikes (MS)	Use	used to assess the effect sample matrix of the spiked sample has on the precision and accuracy of the results generated by the method used;
	Typical Frequency [1]	At a minimum, with each matrix-specific batch of samples processed, an MS is carried through the complete analytical procedure. Unless specified by the client, samples used for spiking are randomly selected and rotated between different client projects. If the mandated or requested test method does not specify the spiking components, the laboratory shall spike all reportable components to be reported in the Laboratory Control Sample and Matrix Spike. Refer to the method SOP for complete details
	Description	essentially a sample fortified with a known amount of the test analyte(s).
Surrogate	Use	Measures method performance to sample matrix (organics only).
	Typical Frequency [1]	Are added to all samples, standards, and blanks, for all organic chromatography methods except when the matrix precludes its use or when a surrogate is not available. The recovery of the surrogates is compared to the acceptance limits for the specific method. Poor surrogate recovery may indicate a problem with sample composition and shall be reported, with data qualifiers, to the client whose sample produced poor recovery.
	Description	Are similar to matrix spikes except the analytes are compounds with properties that mimic the analyte of interest and are unlikely to be found in environment samples.
Duplicates[2]	Use	For a measure of analytical precision, with each matrix-specific batch of samples processed, a matrix duplicate (MD or DUP) sample, matrix spike duplicate (MSD), or LCS duplicate (LCSD) is carried through the complete analytical procedure.
	Typical Frequency [1]	Duplicate samples are usually analyzed with methods that do not require matrix spike analysis.
	Description	Performed by analyzing two aliquots of the same field sample independently or an additional LCS.
Internal Standards	Use	Are spiked into all environmental and quality control samples (including the initial calibration standards) to monitor the qualitative aspect of organic and some inorganic analytical measurements.
	Typical Frequency [1]	All organic and ICP methods as required by the analytical method.
	Description	Used to correct for matrix effects and to help troubleshoot variability in analytical response and are assessed after data acquisition. Possible sources of poor internal standard response are sample matrix, poor analytical technique or instrument performance.

[1] See the specific analytical SOP for type and frequency of sample matrix control samples.

[2] LCSD's are normally not performed except when regulatory agencies or client specifications require them. The recoveries for the spiked duplicate samples must meet the same laboratory established recovery limits as the accuracy QC samples. If an LCSD is analyzed both the LCS and LCSD must meet the same recovery criteria and be included in the final report. The precision measurement is reported as "Relative Percent Difference" (RPD). Poor precision between duplicates (except LCS/LCSD) may indicate non-homogeneous matrix or sampling.

24.6 Acceptance Criteria (Control Limits)

As mandated by the test method and regulation, each individual analyte in the LCS, MS, or Surrogate Spike is evaluated against the control limits published in the test method. Where there are no established acceptance criteria, the laboratory calculates in-house control limits

with the use of control charts or, in some cases, utilizes client project specific control limits. When this occurs, the regulatory or project limits will supersede the laboratory's in-house limits.

Note: For methods, analytes and matrices with very limited data (e.g., unusual matrices not analyzed often), interim limits are established using available data or by analogy to similar methods or matrices.

Once control limits have been established, they are verified, reviewed, and updated if necessary on an annual basis unless the method requires more frequent updating. Control limits are established per method (as opposed to per instrument) regardless of the number of instruments utilized.

Laboratory generated % Recovery acceptance (control) limits are generally established by taking $\pm$ 3 Standard Deviations (99% confidence level) from the average recovery of a minimum of 20-30 data points (more points are preferred).

- Regardless of the calculated limit, the limit should be no tighter than the Calibration Verification (ICV/CCV) (Unless the analytical method specifies a tighter limit).

- In-house limits cannot be any wider than those mandated in a regulated analytical method. Client or contract required control limits are evaluated against the laboratory's statistically derived control limits to determine if the data quality objectives (DQOs) can be achieved. If laboratory control limits are not consistent with DQOs, then alternatives must be considered, such as method improvements or use of an alternate analytical method.

- The lowest acceptable recovery limit will be 10% (the analyte must be detectable and identifiable). Exception: The lowest acceptable recovery limit for Benzidine will be 5% and the analyte must be detectable and identifiable.

- The maximum acceptable recovery limit will be 150%.

- The maximum acceptable RPD limit will be 35% for waters and 40% for soils. The minimum RPD limit is 15%.

- If either the high or low end of the control limit changes by $\leq$ 5% from previous, the control chart is visually inspected and, using professional judgment, they may be left unchanged if there is no effect on laboratory ability to meet the existing limits.

24.6.1 The lab must be able to generate a current listing of their control limits and track when the updates are performed. Current and historical limits are maintained in the LIMS, along with the effective dates. In addition, the laboratory must be able to recreate historical control limits. Refer to laboratory SOP PT-QA-021, *Quality Control Program*, for details on the creation, evaluation and application of statistical control limits.

24.6.2 A LCS that is within the acceptance criteria establishes that the analytical system is in control and is used to validate the process. Samples that are analyzed with an LCS with recoveries outside of the acceptance limits may be determined as out of control and should be reanalyzed if possible. If reanalysis is not possible, then the results for all affected analytes for samples within the same batch must be qualified when reported. The internal corrective action

process (see Section 12) is also initiated if an LCS exceeds the acceptance limits. Sample results may be qualified and reported without reanalysis if:

- The analyte results are below the reporting limit and the LCS is above the upper control limit.

- If the analytical results are above the relevant regulatory limit and the LCS is below the lower control limit. For further detail refer to laboratory SOP PT-QA-021 and method specific SOPs.

- For TNI work, there are an allowable number of Marginal Exceedances (ME):

<11 analytes	0 marginal exceedances are allowed
11 – 30 Analytes	1 marginal exceedance is allowed
31-50 Analytes	2 marginal exceedances are allowed
51-70 Analytes	3 marginal exceedances are allowed
71-90 Analytes	4 marginal exceedances are allowed
> 90 Analytes	5 marginal exceedances are allowed

  - Marginal exceedances are recovery exceedances between 3 SD and 4 SD from the mean recovery limit (TNI).

  - Marginal exceedances must be random. If the same analyte exceeds the LCS control limit repeatedly, it is an indication of a systematic problem. The source of the error must be located and corrective action taken. The laboratory has a system to monitor marginal exceedances to ensure that they are random.

  - Though marginal exceedances may be allowed, the data must still be qualified to indicate it is outside of the normal limits.

24.6.3 If the MS/MSDs do not meet acceptance limits, the MS/MSD and the associated parent sample are reported with a qualifier for those analytes that do not meet limits. If obvious preparation errors are suspected, or if requested by the client, unacceptable MS/MSDs are reprocessed and reanalyzed to prove matrix interference. A more detailed discussion of acceptance criteria and corrective action can be found in SOP No. PT-QA-021 – Laboratory Quality Control Program, analytical method SOPs and in Section 12 of this document.

24.6.4 If a surrogate standard falls outside the acceptance limits, if there is not obvious chromatographic matrix interference, reanalyze the sample to confirm a possible matrix effect. If the recoveries confirm or there was obvious chromatographic interference, results are reported from the original analysis and a qualifier is added. If the reanalysis meets surrogate recovery criteria, the second run is reported (or both are reported if requested by the client). Under certain circumstances, where all of the samples are from the same location and share similar chromatography, the reanalysis may be performed on a single sample rather than all of the samples and if the surrogate meets the recovery criteria in the reanalysis, all of the affected samples would require reanalysis.

24.7 Additional Procedures to Assure Quality Control

The laboratory has written and approved method SOPs to assure the accuracy of the test method including calibration (see Section 20), use of certified reference materials (see Section 21) and use of PT samples (see Section 15).

A discussion regarding MDLs, Limit of Detection (LOD) and Limit of Quantitation (LOQ) can be found in Section 19.

Use of formulae to reduce data is discussed in the method SOPs and in Section 20.

Selection of appropriate reagents and standards is included in Section 9 and 21.

A discussion on selectivity of the test is included in Section 5.

Constant and consistent test conditions are discussed in Section 18.

The laboratories sample acceptance policy is included in Section 23.

SECTION 25

REPORTING RESULTS

25.1 Overview

The results of each test are reported accurately, clearly, unambiguously, and objectively in accordance with State and Federal regulations as well as client requirements. Analytical results are issued in a format that is intended to satisfy customer and laboratory accreditation requirements as well as provide the end user with the information needed to properly evaluate the results. Where there is conflict between client requests and laboratory ethics or regulatory requirements, the laboratory's ethical and legal requirements are paramount, and the laboratory will work with the client during project set up to develop an acceptable solution. Refer to Section 7.

A variety of report formats are available to meet specific needs.

In cases where a client asks for simplified reports, there must be a written request from the client. There still must be enough information that would show any analyses that were out of conformance (QC out of limits) and there should be a reference to a full report that is made available to the client. Review of reported data is included in Section 19.

25.2 Test Reports

Analytical results are reported in a format that is satisfactory to the client and meets all requirements of applicable accrediting authorities and agencies. A variety of report formats are available to meet specific needs. The report is printed on laboratory letterhead, reviewed, and signed by the appropriate project manager. At a minimum, the standard laboratory report shall contain the following information:

25.2.1 A report title (e.g. Analytical Report) on the cover page with a "Result" column header on the sample result page

25.2.2 The cover page shall include the laboratory name, address and telephone number

25.2.3 A unique identification of the report (e.g. Eurofins TestAmerica Job ID#) and on each page an identification in order to ensure the page is recognized as part of the report and a clear identification of the end

Note: Page numbers of report are represented as page # of ## at the bottom of the page. Where the first number is the page number and the second is the total number of pages

25.2.4 A copy of the chain of custody (COC)

- Any COCs involved with Subcontracting are included

25.2.5 The name and address of client and a project name/number, if applicable

25.2.6 Client project manager or other contact

25.2.7 Description and unambiguous identification of the tested sample(s) including the client identification code

25.2.8 Date of receipt of sample, date and time of collection, and date(s) and time of test preparation and performance, and time of preparation or analysis if the required holding time for either activity is less than or equal to 72 hours

25.2.9 Date reported or date of revision, if applicable

25.2.10 Method of analysis including method code (EPA, Standard Methods, etc)

25.2.11 Reporting Limit

25.2.12 Method detection limits (if requested)

25.2.13 Definition of Data qualifiers and reporting acronyms (e.g. ND)

25.2.14 Sample results

25.2.15 QC data consisting of method blank, surrogate, LCS, and MS/MSD recoveries and control limits are included unless the client specifies they do not require reporting the QC

25.2.16 Condition of samples at receipt including temperature. This may be accomplished in the case narrative or by attaching sample login sheets. The temperature is documented on the sample receipt checklist and noted in the report case narrative.

25.2.17 A statement expressing the validity of the results, that the source methodology was followed and all results were reviewed for error

25.2.18 A statement to the effect that the results relate only to the items tested and the sample as received by the laboratory, except when information is provided by the client. When data is provided by the client there shall be a clear indication of it, and a disclaimer shall be put in the report when the client supplied data can affect the validity of the test.

25.2.19 A statement that the report shall not be reproduced except in full, without prior express written approval by the laboratory coordinator

25.2.20 A signature and title of the person(s) accepting responsibility for the content of the report and date of issue (Signatories are appointed by the Lab Director)

25.2.21 When TNI accreditation is required, the lab shall certify that the test results meet all requirements of TNI or provide reasons and/or justification if they do not

25.2.22 If applicable, the laboratory includes a cover letter

25.2.23 Where applicable, a narrative to the report that explains the issue(s) and corrective action(s) taken in the event that a specific accreditation or certification requirement was not met

25.2.24 When soil samples are analyzed, a specific identification as to whether soils are reported on a “wet weight” or “dry weight” basis

25.2.25 Appropriate laboratory certification number for the state of origin of the sample, if applicable

25.2.26 If only part of the report is provided to the client (client requests some results before all of it is complete), it must be clearly indicated on the report (e.g., preliminary report). A complete report must be sent once all of the work has been completed.

25.2.27 Any non-Eurofins TestAmerica subcontracted analysis results are provided as a separate report on the official letterhead of the subcontractor. All Eurofins TestAmerica subcontracting is clearly identified on the report as to which laboratory performed a specific analysis.

25.2.28 A clear statement notifying the client that non-accredited tests were performed and directing the client to the laboratory’s accreditation certificates of approval shall be provided when non-accredited tests are included in the report.

25.2.29 Where the laboratory is responsible for the sampling stage, in addition to the requirements listed above, reports containing the results of sampling shall include the following, where necessary for the interpretation of test results:

- The date of sampling
- Unambiguous identification of the material sampled
- The location of sampling
- A reference to the sampling plan and procedures, and deviations, additions to or exclusions from the sampling procedures
- Details of any environmental conditions during sampling that affect the interpretation of test results
- Information required to evaluate measurement uncertainty for subsequent testing

Note: It is required by the PA DEP that non-accredited parameters be clearly identified on the sample results.

Note: Refer to the Corporate SOP on Electronic Reporting and Signature Policy (No. CA-I-P-002) for details on internally applying electronic signatures of approval.

25.3 Reporting Level Or Report Type

The laboratory offers four levels of quality control reporting. Each level, in addition to its own specific requirements, contains all the information provided in the preceding level. The packages provide the following information in addition to the information described above:

- Level I is a report with the features described in Section 25.2 above.
- Level II is a Level I report plus summary information, including results for the method blank reported to the laboratory MDL, percent recovery for laboratory control samples and matrix spike samples, and the RPD values for all MSD and sample duplicate analyses.
- Level III contains all the information supplied in Level II, but presented on the CLP-like summary forms, and relevant calibration information. A Level II report is not included, unless specifically requested. No raw data is provided.
- Level IV is the same as Level III with the addition of all raw supporting data.

In addition to the various levels of QC packaging, the laboratory also provides reports in diskette deliverable form. Initial reports may be provided to clients by facsimile. Procedures used to ensure client confidentiality are outlined in Section 25.6.

25.3.1 Electronic Data Deliverables (EDDs)

EDDs are routinely offered as part of Eurofins TestAmerica's services in addition to the test report as described in section 25.2. When NELAP accreditation is required and both a test report and EDD are provided to the client, the official version of the test report will be the combined information of the report and the EDD. Data qualifiers appearing on the test report must be included in the EDD.

Pittsburgh offers a variety of EDD formats including Environmental Restoration Information Management System (ERPIMS), Staged Electronic Data Deliverable (SEDD) Environmental Quality Information System (EQuIS), Electronic Deliverable Format (EDF), Excel and custom files as requested by the client.

EDD specifications are submitted to the IT department by the PM for review and undergo the contract review process. Once the facility has committed to providing data in a specific

electronic format, the coding of the format may need to be performed. This coding is documented and validated. The validation of the code is retained by the IT staff coding the EDD.

EDDs shall be subject to a review to ensure their accuracy and completeness. If EDD generation is automated, review may be reduced to periodic screening if the laboratory can demonstrate that it can routinely generate that EDD without errors. Any revisions to the EDD format must be reviewed until it is demonstrated that it can routinely be generated without errors. If the EDD can be reproduced accurately and if all subsequent EDDs can be produced error-free, each EDD does not necessarily require a review.

25.4 Supplemental Information For Test

The lab identifies any unacceptable QC analyses or any other unusual circumstances or observations such as environmental conditions and any non-standard conditions that may have affected the quality of a result. This is typically in the form of a footnote or a qualifier and/or a narrative explaining the discrepancy in the front of the report.

Numeric results with values outside of the calibration range, either high or low are qualified as estimated.

Where quality system requirements are not met, a statement of compliance/non-compliance with requirements and/or specifications is required, including identification of test results derived from any sample that did not meet TNI sample acceptance requirements such as improper container, holding time, or temperature.

Where applicable, a statement on the estimated uncertainty of measurements; information on uncertainty is needed when a client's instructions so require.

When, as required by the client and agreed to by Eurofins TestAmerica, the report includes a statement of conformity to specification or standard (see Special Services, Section 7.4), the report shall clearly identify:

- To which results the statement applies
- Which specifications, standard or parts thereof are met or not
- The decision rule that was applied unless the decision rule is inherent in the requested specification or standard, taking into account the level of risk (such as false accept and false reject and statistical assumptions) associated with the decision rule.

Opinions and Interpretations - The test report contains objective information, and generally does not contain subjective information such as opinions and interpretations. If such information is required by the client, the Laboratory Director will determine if a response can be prepared. If so, the Laboratory Director will designate the appropriate member of the management team to prepare a response. The response will be fully documented, and reviewed by the Laboratory Director, before release to the client. There may be additional fees charged to the client at this time, as this is a non-routine function of the laboratory.

Note: Review of data deliverable packages for submittal to regulatory authorities requires responses to non-conforming data concerning potential impact on data quality. This necessitates a limited scope of interpretation, and this work is performed by the

Manager(s)/Team Leaders or as assigned by the lab Director. This is the only form of "interpretation" of data that is routinely performed by the laboratory.

When opinions or interpretations are included in the report, the laboratory provides an explanation as to the basis upon which the opinions and interpretations have been made. Opinions and interpretations are clearly noted as such and where applicable, a comment should be added suggesting that the client verify the opinion or interpretation with their regulator.

25.5 Environmental Testing Obtained From Subcontractors

If the laboratory is not able to provide the client the requested analysis, the samples would be subcontracted following the procedures outlined in the Corporate SOP on Subcontracting (SOP # CW-L-S-004).

Data reported from analyses performed by a subcontractor laboratory are clearly identified as such on the analytical report provided to the client. Results from a subcontract laboratory outside of Eurofins TestAmerica are reported to the client on the subcontract laboratory's original report stationary and the report includes any accompanying documentation.

25.6 Client Confidentiality

Eurofins TestAmerica is responsible for maintaining in confidence all client information obtained or created. In situations involving the transmission of environmental test results by telephone, facsimile or other electronic means, client confidentiality must be maintained.

Eurofins TestAmerica will not intentionally divulge to any person (other than the Client or any other person designated by the Client in writing) any information regarding the services provided by Eurofins TestAmerica or any information disclosed to Eurofins TestAmerica by the Client. Furthermore, information known to be potentially endangering to national security or an entity's proprietary rights will not be released.

Information about the client obtained from sources other than the client (r.g, complaint, regulators) shall be confidential between client and laboratory. The source of this information shall be confidential to the laboratory and shall not be shared with the client, unless agreed to by the source.

Note: This shall not apply to the extent that the information is required to be disclosed by Eurofins TestAmerica under the compulsion of legal process. Eurofins TestAmerica will, to the extent feasible, provide reasonable notice to the client before disclosing the information.

Note: Authorized representatives of an accrediting authority are permitted to make copies of any analyses or records relevant to the accreditation process, and copies may be removed from the laboratory for purposes of assessment.

25.6.1 Report deliverable formats are discussed with each new client. If a client requests that reports be faxed or e-mailed, the reports are to meet all requirements of this document, including a cover letter.

25.7 Format Of Reports

The format of reports is designed to accommodate each type of environmental test carried out and to minimize the possibility of misunderstanding or misuse.

25.8 Amendments To Test Reports

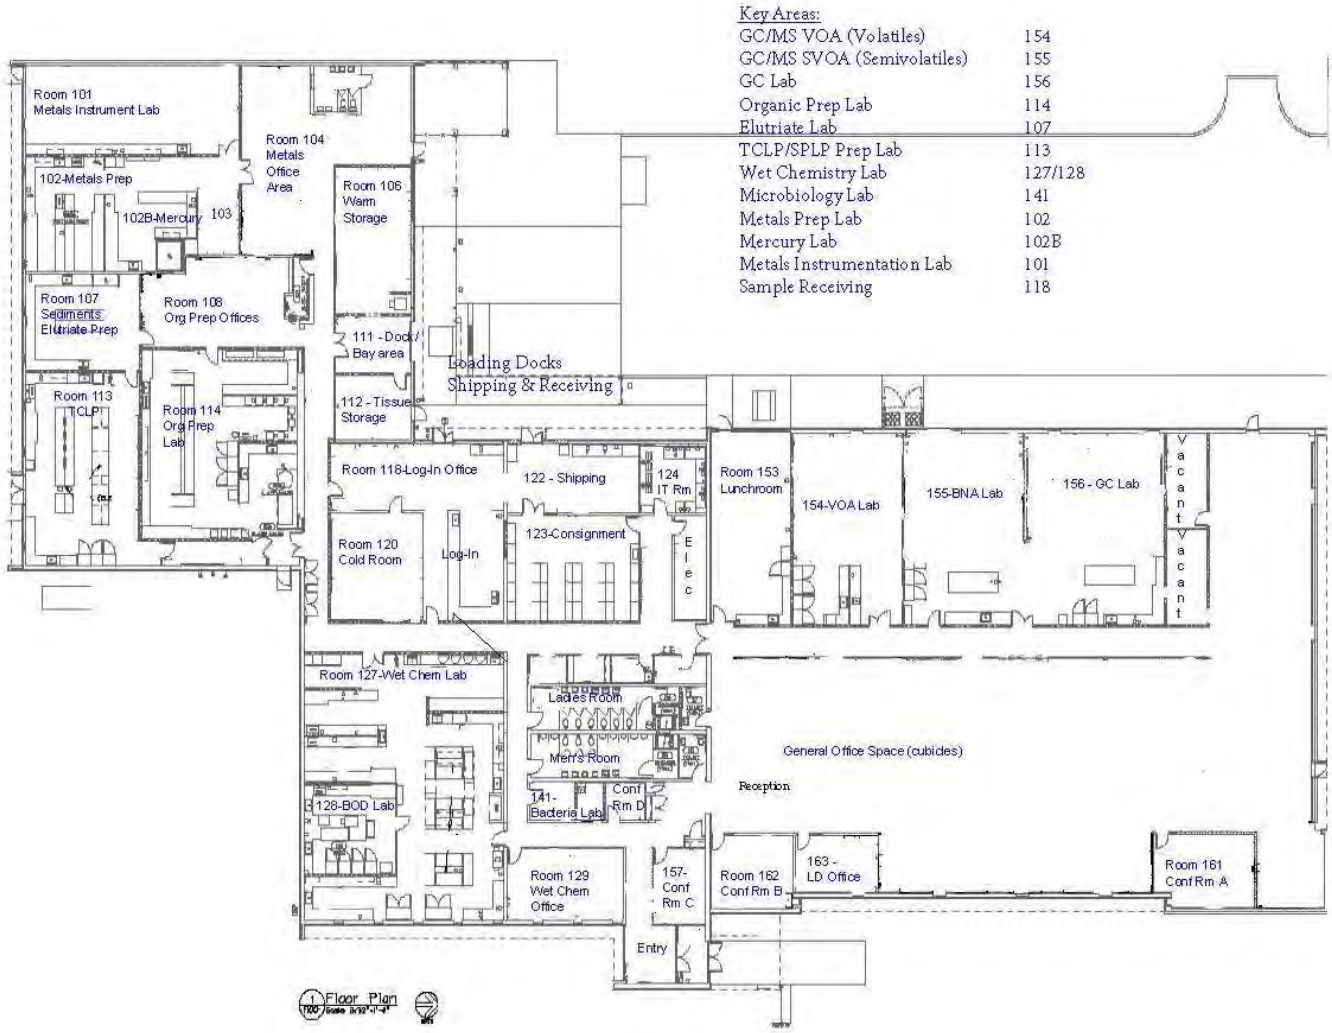
Corrections, additions, or deletions to reports are only made when justification arises through supplemental documentation. Justification is documented using the laboratory's corrective action system (refer to Section 12).

The revised report is retained on the data server, as is the original report. The revised report is stored in the data server under the job number followed by "Rev (n)" where 'n' is the revision number. The revised report will have the words "Revision (n)" on the report cover page beneath the report date.

When the report is re-issued, a notation of "report re-issue" is placed on the cover/signature page of the report or at the top of the narrative page with a brief explanation of reason for the re-issue and a reference back to the last final report generated.

25.9 Policies On Client Requests For Amendments

25.9.1 Policy on Data Omissions or Reporting Limit Increases



Fundamentally, our policy is simply to not omit previously reported results (including data qualifiers) or to not raise reporting limits and report sample results as ND. This policy has few exceptions. Exceptions are:

- Laboratory error
- Sample identification is indeterminate (confusion between COC and sample labels)
- An incorrect analysis (not analyte) was requested (e.g., COC lists 8315 but client wanted 8310). A written request for the change is required.
- Incorrect limits reported based on regulatory requirements
- The requested change has absolutely *no possible* impact on the interpretation of the analytical results and there is *no possibility* of the change being interpreted as misrepresentation by anyone inside or outside of our company.

25.9.2 Multiple Reports

Eurofins TestAmerica does not issue multiple reports for the same job number where there is different information on each report (this does not refer to copies of the same report) unless required to meet regulatory needs and approved by QA.

Appendix 1
Laboratory Floor Plan

Appendix 2
Glossary/Acronyms

Glossary:

Acceptance Criteria: Specified limits placed on characteristics of an item, process, or service defined in requirement documents. (ASQC)

Accreditation: The process by which an agency or organization evaluates and recognizes a laboratory as meeting certain predetermined qualifications or standards, thereby accrediting the laboratory.

Accuracy: The degree of agreement between an observed value and an accepted reference value. Accuracy includes a combination of random error (precision) and systematic error (bias) components which are due to sampling and analytical operations; a data quality indicator. (QAMS)

Analyst: The designated individual who performs the "hands-on" analytical methods and associated techniques and who is the one responsible for applying required laboratory practices and other pertinent quality controls to meet the required level of quality. (TNI)

Analytical Uncertainty: A subset of Measurement Uncertainty that includes all laboratory activities performed as part of the analysis. (TNI)

Anomaly: A condition or event, other than a deficiency, that may affect the quality of the data, whether in the laboratory's control or not.

Assessment: The evaluation process used to measure or establish the performance, effectiveness, and conformance of an organization and/or its systems to defined criteria (to the standards and requirements of laboratory accreditation). (TNI)

Audit: A systematic and independent examination of facilities, equipment, personnel, training, procedures, record-keeping, data validation, data management, and reporting aspects of a system to determine whether QA/QC and technical activities are being conducted as planned and whether these activities will effectively achieve quality objectives. (TNI)

Batch: Environmental samples which are prepared and/or analyzed together with the same process and personnel, using the same lot(s) of reagents. A **preparation batch** is composed of one to 20 environmental samples of the same matrix, meeting the above mentioned criteria and with a maximum time between the start of processing of the first and last sample in the batch to be 24 hours. An **analytical batch** is composed of prepared environmental samples (extracts, digestates or concentrates) which are analyzed together as a group. An analytical batch can include prepared samples originating from various quality system matrices and can exceed twenty (20) samples. (TNI)

Bias: The systematic or persistent distortion of a measurement process, which causes errors in one direction (i.e., the expected sample measurement is different from the sample's true value). (TNI)

Blank: A sample that has not been exposed to the analyzed sample stream in order to monitor contamination during sampling, transport, storage or analysis. The blank is subjected to the usual analytical and measurement process to establish a zero baseline or background value and is sometimes used to adjust or correct routine analytical results. (ASQC)

Calibration: A set of operations that establish, under specified conditions, the relationship between values of quantities indicated by a measuring instrument or measuring system, or values represented by a material measure or a reference material, and the corresponding values realized by standards. (TNI)

1) In calibration of support equipment the values realized by standards are established through the use of reference standards that are traceable to the International System of Units (SI).

2) In calibration according to methods, the values realized by standards are typically established through the use of Reference Materials that are either purchased by the laboratory with a certificate of analysis or purity, or prepared by the laboratory using support equipment that has been calibrated or verified to meet specifications.

Calibration Curve: The mathematical relationship between the known values, such as concentrations, of a series of calibration standards and their instrument response. (TNI)

Calibration Standard: A substance or reference material used to calibrate an instrument (QAMS)

Certified Reference Material (CRM): A reference material, accompanied by a certificate, having a value, measurement uncertainty, and stated metrological traceability chain to a national metrology institute. (TNI)

Chain of Custody (COC) Form**:** Record that documents the possession of the samples from the time of collection to receipt in the laboratory. This record generally includes: the number and types of containers; the mode of collection; the collector; time of collection; preservation; and requested analyses. (TNI)

Compromised Samples: Those samples which are improperly sampled, insufficiently documented (chain of custody and other sample records and/or labels), improperly preserved, collected in improper containers, or exceeding holding times when delivered to a laboratory. Under normal conditions, compromised samples are not analyzed. If emergency situation require analysis, the results must be appropriately qualified.

Confidential Business Information (CBI): Information that an organization designates as having the potential of providing a competitor with inappropriate insight into its management, operation or products. TNI and its representatives agree to safeguarding identified CBI and to maintain all information identified as such in full confidentiality.

Confirmation: Verification of the identity of a component through the use of an approach with a different scientific principle from the original method. These may include, but are not limited to Second Column Confirmation; Alternate wavelength; Derivatization; Mass spectral interpretation; Alternative detectors or Additional Cleanup procedures. (TNI)

Conformance: An affirmative indication or judgment that a product or service has met the requirements of the relevant specifications, contract, or regulation; also the state of meeting the requirements. (ANSI/ASQC E4-1994)

Correction*:* Actions necessary to correct or repair analysis specific non-conformances. The acceptance criteria for method specific QC and protocols as well as the associated corrective actions. The analyst will most frequently be the one to identify the need for this action as a result of calibration checks and QC sample analysis**.** No significant action is taken to change behavior, process or procedure.

Corrective Action: The action taken to eliminate the causes of an existing nonconformity, defect or other undesirable situation in order to prevent recurrence. (ISO 8402)

Data Audit: A qualitative and quantitative evaluation of the documentation and procedures associated with environmental measurements to verify that the resulting data re of acceptable quality (i.e., that they meet specified acceptance criteria). (TNI)

Data Reduction: The process of transforming the number of data items by arithmetic or statistical calculations, standard curves, and concentration factors, and collation into a more useable form. (TNI)

Data Review Checker: Automated data review feature in TALS that compares data entered to list of control and preventative review requirements and presents all findings to the first level data reviewer for response or correction.

Deficiency: An unauthorized deviation from acceptable procedures or practices, or a defect in an item. (ASQC), whether in the laboratory's control or not.

Demonstration of Capability: A procedure to establish the ability of the analyst to generate analytical results of acceptable accuracy and precision. (TNI)

Document Control: The act of ensuring that documents (and revisions thereto) are proposed, reviewed for accuracy, approved for release by authorized personnel, distributed properly, and controlled to ensure use of the correct version at the location where the prescribed activity if performed. (ASQC)

Duplicate Analyses: The analyses or measurements of the variable of interest performed identically on two subsamples of the same sample. The results from duplicate analyses are used to evaluate analytical or measurement precision but not the precision of sampling, preservation or storage internal to the laboratory. (EPA-QAD)

Equipment Blank: Sample of analyte-free media which has been used to rinse common sampling equipment to check effectiveness of decontamination procedures.

External Standard Calibration: Calibrations for methods that do not utilize internal standards to compensate for changes in instrument conditions.

Field Blank: Blank prepared in the field by filing a clean container with pure de-ionized water and appropriate preservative, if any, for the specific sampling activity being undertaken (EPA OSWER)

Field of Accreditation: Those matrix, technology/method, and analyte combinations for which the accreditation body offers accreditation.

Holding Times : The maximum times that samples may be held prior to analyses and still be considered valid or not compromised. (40 CFR Part 136)

Internal Standard: A known amount of standard added to a test portion of a sample as a reference for evaluating and controlling the precision and bias of the applied analytical test method. (TNI)

Internal Standard Calibration: Calibrations for methods that utilize internal standards to compensate for changes in instrument conditions.

Instrument Blank: A clean sample (e.g., distilled water) processed through the instrumental steps of the measurement process; used to determine instrument contamination. (EPA-QAD)

Instrument Detection Limit (IDL): The minimum amount of a substance that can be measured with a specified degree of confidence that the amount is greater than zero using a specific instrument. The IDL is associated with the instrumental portion of a specific method only, and sample preparation steps are not considered in its derivation. The IDL is a statistical estimation at a specified confidence interval of the concentration at which the relative uncertainty is ± 100%. The IDL represents a range where qualitative detection occurs on a specific instrument. Quantitative results are not produced in this range.

Laboratory Control Sample (however named, such as laboratory fortified blank, spiked blank, or QC check sample): A sample matrix, free from the analytes of interest, spiked with verified known amounts of analytes or a material containing known and verified amounts of analytes, taken through all preparation

and analysis steps of the procedure unless otherwise noted in a reference method. It is generally used to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.

An LCS shall be prepared at a minimum of 1 per batch of 20 or less samples per matrix type per sample extraction or preparation method, or more frequently if so required by the reference method, except for analytes for which spiking solutions are not available such as, total volatile solids, odor, temperature, or dissolved oxygen. The results of these samples shall be used to determine batch acceptance.

Least Squares Regression (1st Order Curve): The least squares regression is a mathematical calculation of a straight line over two axes. The y axis represents the instrument response (or Response ratio) of a standard or sample and the x axis represents the concentration. The regression calculation will generate a correlation coefficient (r) that is a measure of the "goodness of fit" of the regression line to the data. A value of 1.00 indicates a perfect fit. In order to be used for quantitative purposes, r must be greater than or equal to 0.99 for organics and 0.995 for inorganics.

Limit of Detection (LOD): [a.k.a., Method Detection Limit (MDL]: The MDL is the minimum measured quantity of a substance that can be reported with 99% confidence that the concentration is distinguishable from method blank results, consistent with 40CFR Part 136 Appendix B, August, 2017.

Limit(s) of Quantitation (LOQ) [a.k.a., Reporting Limit]: The minimum levels, concentrations, or quantities of a target variable (e.g., target analyte) that can be reported with a specified degree of confidence. (TNI)

(QS) Matrix: The component or substrate that contains the analyte of interest. For purposes of batch and QC requirement determinations, the following matrix distinctions shall be used:

Aqueous: Any aqueous sample excluded from the definition of Drinking Water or Saline/Estuarine. Includes surface water, groundwater, effluents, and TCLP or other extracts.

Drinking Water: any aqueous sample that has been designated as a potable or potential potable water source.

Saline/Estuarine: any aqueous sample from an ocean or estuary, or other salt water source such as the Great Salt Lake.

Non-aqueous Liquid: any organic liquid with <15% settleable solids.

Biological Tissue: any sample of a biological origin such as fish tissue, shellfish, or plant material. Such samples shall be grouped according to origin.

Solids: includes soils, sediments, sludges, and other matrices with >15% settleable solids.

Chemical Waste: a product or by-product of an industrial process that results in a matrix not previously defined.

Air *& Emissions*: whole gas or vapor samples including those contained in flexible or rigid wall containers and the extracted concentrated analytes of interest from a gas or vapor that are collected with a sorbant tube, impinger solution, filter, or other device. (TNI)

Matrix Spike (spiked sample or fortified sample): A sample prepared, taken through all sample preparation and analytical steps of the procedure unless otherwise noted in a referenced method, by adding a known amount of target analyte to a specified amount of sample for which an independent test result of target analyte concentration is available. Matrix spikes are used, for example, to determine the effect of the matrix on a method's recovery efficiency.

Matrix Spike Duplicate (spiked sample or fortified sample duplicate): A replicate matrix spike prepared and analyzed to obtain a measure of the precision of the recovery for each analyte.
Method Blank: A sample of a matrix similar to the batch of associated samples (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences are present at concentrations that impact the analytical results for sample analyses.

Method Detection Limit: See Limit of Detection (LOD)

Negative Control: Measures taken to ensure that a test, its components, or the environment do not cause undesired effects, or produce incorrect test results.

Non-conformance**:** An indication, judgment, or state of not having met the requirements of the relevant specifications, contract, or regulation.

Observation: A record of phenomena that (1) may assist in evaluation of the sample data; (2) may be of importance to the project manager and/or the client, and yet not at the time of the observation have any known effect on quality.

Performance Audit: The routine comparison of independently obtained qualitative and quantitative measurement system data with routinely obtained data in order to evaluate the proficiency of an analyst or laboratory.

Positive Control: Measures taken to ensure that a test and/or its components are working properly and producing correct or expected results from positive test subjects.

Precision: The degree to which a set of observations or measurements of the same property, obtained under similar conditions, conform to themselves; a data quality indicator. Precision is usually expressed as standard deviation, variance or range, in either absolute or relative terms.

Preservation: Any conditions under which a sample must be kept in order to maintain chemical and/or biological integrity prior to analysis. (TNI)

Proficiency Testing: A means of evaluating a laboratory's performance under controlled conditions relative to a given set of criteria through analysis of unknown samples provided by an external source. (TNI)

Proficiency Testing Program: The aggregate of providing rigorously controlled and standardized environmental samples to a laboratory for analysis, reporting of results, statistical evaluation of the results and the collective demographics and results summary of all participating laboratories. (TNI)

Proficiency Test Sample (PT): A sample, the composition of which is unknown to the laboratory and is provided to test whether the analyst/laboratory can produce analytical results within specified acceptance criteria. (TNIS)

Quality Assurance: An integrated system of management activities involving planning, implementation, assessment,~~,~~ reporting and quality improvement to ensure that a process, item, ~~product~~ or service is of the type of quality needed and expected by the client. (TNI)

Quality Assurance [Project] Plan (QAPP): A formal document describing the detailed quality control procedures by which the quality requirements defined for the data and decisions pertaining to a specific project are to be achieved. (EAP-QAD)

Quality Control: The overall system of technical activities that measures the attributes and performance of a process, item, or service against defined standards to verify that they meet the stated requirements established by the customer; operational techniques and activities that are used to fulfill requirements for quality; also the system of activities and checks used to ensure that measurement systems are maintained within prescribed limits, providing protection against “out of control” conditions and ensuring that the results are of acceptable quality. (TNI)

Quality Control Sample: A sample used to assess the performance of all or a portion of the measurement system. One of any number of samples, such as Certified Reference Materials, a quality system matrix fortified by spiking, or actual samples fortified by spiking, intended to demonstrate that a measurement system or activity is in control. (TNI)

Quality Manual: A document stating the management policies, objectives, principles, organizational structure and authority, responsibilities, accountability, and implementation of an agency, organization, or laboratory, to ensure the quality of its product and the utility of its product to its users. (TNI)

Quality System: A structured and documented management system describing the policies, objectives, principles, organizational authority, responsibilities, accountability, and implementation plan of an organization for ensuring quality in its work processes, products (items), and services. The quality system provides the framework for planning, implementing, and assessing work performed by the organization and for carrying out required QA and QC activities. (TNI)

Raw Data: The documentation generated during sampling and analysis. This documentation includes, but is not limited to, field notes, electronic data, magnetic tapes, untabulated sample results, QC sample results, print outs of chromatograms, instrument outputs, and handwritten records. (TNI)

Record Retention: The systematic collection, indexing and storing of documented information under secure conditions.

Reference Material: Material or substance one or more properties of which are sufficiently homogeneous and well established to be used for the calibration of an apparatus, the assessment of a measurement method, or for assigning values to materials. (ISO Guide 30-2.1)

Reference Standard: Standard used for the calibration of working measurement standards in a given organization or a given location. (TNI)

Sampling: Activity related to obtaining a representative sample of the object of conformity assessment, according to a procedure.

Second Order Polynomial Curve (Quadratic): The 2^{nd} order curves are a mathematical calculation of a slightly curved line over two axis. The y axis represents the instrument response (or Response ratio) of a standard or sample and the x axis represents the concentration. The 2^{nd} order regression will generate a coefficient of determination (COD or r^2) that is a measure of the "goodness of fit" of the quadratic curvature the data. A value of 1.00 indicates a perfect fit. In order to be used for quantitative purposes, r^2 must be greater than or equal to 0.99.

Selectivity: The ability to analyze, distinguish, and determine a specific analyte or parameter from another component that may be a potential interferent or that may behave similarly to the target analyte or parameter within the measurement system. (TNI)

Sensitivity: The capability of a method or instrument to discriminate between measurement responses representing different levels (e.g., concentrations) of a variable of interest. (TNI)

Spike: A known mass of target analyte added to a blank, sample or sub-sample; used to determine recovery efficiency or for other quality control purposes.

Standard: The document describing the elements of laboratory accreditation that has been developed and established within the consensus principles of standard setting NELAC and meets the approval requirements of standard adoption organizations procedures and policies. (TNI)

Standard Operating Procedures (SOPs): A written document which details the method for an operation, analysis, or action, with thoroughly prescribed techniques and steps. SOPs are officially approved as the methods for performing certain routine or repetitive tasks. (TNI)

Storage Blank: A blank matrix stored with field samples of a similar matrix (volatiles only) that measures storage contribution to any source of contamination.

Surrogate: A substance with properties that mimic the analyte of interest. It is unlikely to be found in environment samples and is added to them for quality control purposes.

Surrogate compounds must be added to all samples, standards, and blanks, for all organic chromatography methods except when the matrix precludes its use or when a surrogate is not available. Poor surrogate recovery may indicate a problem with sample composition and shall be reported to the client whose sample produced poor recovery. (QAMS)

Systems Audit (also Technical Systems Audit): A thorough, systematic, qualitative on-site assessment of the facilities, equipment, personnel, training, procedures, record keeping, data validation, data management, and reporting aspects of a total measurement system. (EPA-QAD)

Technical Manager: A member of the staff of an environmental laboratory who exercises actual day-to-day supervision of laboratory operations for the appropriate fields of accreditation and reporting of results

Technology: A specific arrangement of analytical instruments, detection systems, and/or preparation techniques.

Traceability: The ability to trace the history, application, or location of an entity by means of recorded identifications. In a calibration sense, traceability relates measuring equipment to national or international standards, primary standards, basic physical constants or properties, or reference materials. In a data collection sense, it relates calculations and data generated throughout the project back to the requirements for the quality of the project. (TNI)

Trip Blank:
A blank matrix placed in a sealed container at the laboratory that is shipped, held unopened in the field, and returned to the laboratory in the shipping container with the field samples.

Uncertainty:
A parameter associated with the result of a measurement that characterizes the dispersion of the value that could reasonably be attributed to the measured value.

Acronyms:

CAR – Corrective Action Report
CCV – Continuing Calibration Verification
CF – Calibration Factor
CFR – Code of Federal Regulations
COC – Chain of Custody
DOC – Demonstration of Capability
DQO – Data Quality Objectives
DUP - Duplicate
EHS – Environment, Health and Safety
EPA – Environmental Protection Agency
GC - Gas Chromatography
GC/MS - Gas Chromatography/Mass Spectrometry
HPLC - High Performance Liquid Chromatography
ICP - Inductively Coupled Plasma Atomic Emission Spectroscopy
ICP/MS – ICP/Mass Spectrometry
ICV – Initial Calibration Verification
IDL – Instrument Detection Limit
IH – Industrial Hygiene
IS – Internal Standard
LCS – Laboratory Control Sample
LCSD – Laboratory Control Sample Duplicate
LIMS – Laboratory Information Management System
LOD – Limit of Detection
LOQ – Limit of Quantitation
MDL – Method Detection Limit
MDLCK – MDL Check Standard
MDLV – MDL Verification Check Standard
MRL – Method Reporting Limit Check Standard
MS – Matrix Spike
MSD – Matrix Spike Duplicate
MSDS - Material Safety Data Sheet
NELAP - National Environmental Laboratory Accreditation Program
PT – Performance Testing
TNI – The NELAC Institute
QAM – Quality Assurance Manual
QA/QC – Quality Assurance / Quality Control
QAPP – Quality Assurance Project Plan
RF – Response Factor
RPD – Relative Percent Difference
RSD – Relative Standard Deviation
SD – Standard Deviation
SOP: Standard Operating Procedure
TAT – Turn-Around-Time
VOA – Volatiles
VOC – Volatile Organic Compound

Appendix 3

Laboratory Certifications, Accreditations, Validations

Pittsburgh maintains certifications, accreditations, certifications, and validations with numerous state and national entities. Programs vary but may include on-site audits, reciprocal agreements with another entity, performance testing evaluations, review of the QA Manual, Standard Operating Procedures, Method Detection Limits, training records, etc. At the time of this QA Manual revision, the laboratory has accreditation / certification / licensing with the following organizations:

Organization	Certificate Number Or Laboratory ID Number
Arkansas	88-0690
California ELAP	2891
Connecticut	PH-0688
Florida	E871008
Illinois	002602
Kansas	E-10350
Kentucky	KY98043
Louisiana	04041
Maine	2020007
Minnesota	042-999-482
Nevada	PA00164
New Hampshire	203010
New Jersey	PA005
New York	11182
North Carolina	434
North Dakota	R-227
Oregon	PA-2151
Pennsylvania	02-00416
Rhode Island	LAO00362
South Carolina	89014002
Texas	T104704528
Utah	STLP
USDA	P330-10-00139
USDA	P-Soil -01
Virginia VELAP	460189
West Virginia	142
Wisconsin	998027800

The certificates and parameter lists (which may differ) are available, upon request, from a laboratory representative. They may be found on the Corporate web site, the laboratory's public server and in the QA web page.

Appendix 4

Pittsburgh Laboratory SOP List

Document No.	Title
PT-FS-001	Field Measurement of Dissolved Oxygen (DO) Method: SM 4500-O G
PT-FS-002	Field Measurement of Total Residual Chlorine Method: SM 4500-Cl G
PT-FS-003	Field Measurement of pH Method: SM 4500 H+B
PT-FS-004	General Sampling Instructions
PT-GC-001	Gas Chromatographic Analysis of Herbicides, SW-846 Method 8151A
PT-GC-002	Analysis of Organochlorine Pesticides and PCBs by Method 608
PT-GC-004	1,2-Dibromoethane(EDB) and 1,2-Dibromo-3-Chloropropane(DBCP) in Water by Microextraction and Gas Chromatography, Method 8011
PT-GC-005	Polychlorinated Biphenyls (PCBs) and PCBs as Congeners by GC/ECD - Method: SW-846 8082 and 8082A
PT-GC-006	Chlorinated Pesticides - Method: SW-846 8081A/B
PT-GC-007	Organophosphorus Pesticides by Gas Chromatography - Method: SW-846 8141A and 8141B
PT-GC-009	Determination of Inorganic Anions by Ion Chromatography EPA Method 300 SW-846 Method 9056A
PT-GC-010	TOC Analysis for Solids by Lloyd Kahn Method
PT-GC-013	Determination of Particulate Organic Carbon in Sediment and Estuarine / Coastal Water Matrices
PT-GC-014	Halogenated Organic Compounds by Direct Injection GC/ECD
PT-GC-015	Analysis of Organochlorine Pesticides and PCBs by EPA Method 608.3
PT-HS-001	Pittsburgh Facility Addendum to Eurofins TestAmerica Corporate Environmental Health & Safety Manual (CW-E-M-001)
PT-HS-002	Bloodborne Pathogen Exposure Control Path
PT-IP-002	Acid Digestion of Soils, SW-846 Method 3050B
PT-IP-003	Acid Digestion of Aqueous Samples by SW-846 Methods 3005A, 3010A and EPA Methods 200.7 and 200.8
PT-IT-001	Data Backup Procedures
PT-MI-001	Total Coliforms and E. coli – Presence/Absence Test Using Colilert
PT-MS-001	Semivolatile Organic Anaysis by GC/MS, Method 625
PT-MS-002	Volatile Organics by GC/MS Based on Method 624
PT-MS-005	VOA Holding Blanks

Document No.	Title
PT-MS-008	GC/MS Analysis for Semivolatile Organics, Methods: SW-846 8270C & D
PT-MS-010	Determination of Volatile Organics by GC/MS Methods: SW-846 8260B & C
PT-MS-011	Semivolatile Organic Analysis by GCMS, EPA Method 625.1
PT-MS-012	Volatile Organic Analysis by GCMS, EPA Method 624.1
PT-MT-001	Inductively Coupled Plasma-Atomic Emission Spectroscopy, Spectrometric Method for Trace Element Analyses, SW-846 Method 6010B, 6010C, 6010D and EPA Method 200.7
PT-MT-002	Analysis of Metals by Inductively Coupled Plasma/Mass Spectrometry (ICPMS) for Methods 200.8, 6020, 6020A
PT-MT-005	Preparation and Analysis of Mercury by Cold Vapor Atomic Absorption
PT-OP-001	Extraction and Cleanup of Organic Compounds from Waters and Solids, Based on SW-846 3500 and 600 Series Methods
PT-OP-002	Simplified Laboratory Runoff Procedure (SLRP)
PT-OP-003	Standard Elutriate Test (SET)
PT-OP-004	Toxicity Characteristic Leaching Procedure and Synthetic Precipitation Leaching Procedure
PT-OP-005	Modified and Effluent Elutriate Tests (MET and EET)
PT-OP-006	Long Tube Column Settling Test
PT-OP-007	Illinois Re-suspension Tests
PT-OP-008	Dredging Elutriate Test (DRET)
PT-OP-009	Sequential Batch Leach Test (SBLT) for Freshwater Sediments
PT-OP-011	Extractable Residue (Lipids) from Animal Tissue
PT-OP-015	Modified Multiple Extraction Procedure Method: SW-846 1320
PT-OP-016	Porewater Generation
PT-OP-017	Liquid-Solid Partitioning as a Function of Extract pH in Solid Materials using a Parallel Batch Procedure SW-846 Method 1313
PT-OP-018	Liquid-Solid Partitioning as a Function of Liquid-to-Solid Ratio in Solid Materials using a Parallel Batch Procedure SW-846 Method 1316
PT-OP-019	Mass Transfer Rates of Constituents in Monolithic or Compacted Granular Materials using a Semi-Dynamic Tank Leaching Procedure SW-846 Method 1315
PT-OP-020	Standard Test Method for 24-h Batch-Type Measurement of Contaminant Sorption by Soils and Sediments ASTM D4646-03
PT-OP-021	Liquid-Solid Partitioning as a Function of Liquid-to-Solid Ratio for Constituents in Solid Materials using an Up-Flow Percolation Column Procedure SW-846 Method 1314

Document No.	Title
PT-OP-022	Low Volume Extraction and Cleanup of Organic Compounds from Waters Method: SW846 3500 Series
PT-OP-023	Measurement of the Leachability of Solidified Wastes by a Short Term Test Procedure Modified ANSI/ANS-16.1-2003
PT-OP-025	Soil/Sediment Amendment Procedure
PT-OP-026	Extraction of Organic Compounds from Solids, Sediments, Tissues, and Wipes Based on SW-846 3500 Series Methods
PT-OP-027	Extraction of Herbicides by SW846 Method 8151A
PT-OP-028	Clean-up of Organic Extracts by SW-846 3600 Series Methods
PT-OP-030	Handling and Preparation of Biota and Tissue Samples
PT-OP-031	Australian Standard Leaching Procedure - AS 4439.3-1997
PT-QA-001	Employee Orientation & Training
PT-QA-002	Internal Auditing
PT-QA-003	Glassware Clean-up for Organic/Inorganic Procedures
PT-QA-004	Quarantine Soil Procedure
PT-QA-005	Measurement Uncertainty
PT-QA-006	Procurement of Standards and Materials; Labeling and Traceability
PT-QA-007	Detection Limits
PT-QA-008	Thermometer and Barometer Calibration and Temperature Monitoring
PT-QA-009	Rounding and Significant Figures
PT-QA-010	Document Development and Control
PT-QA-012	Selection and Calibration of Balances and Weights
PT-QA-013	Independent QA Data Review
PT-QA-014	Reporting Limits
PT-QA-016	Nonconformance & Corrective Action System
PT-QA-017	Aqueous Pipette Calibration – Gravimetric Method
PT-QA-018	Technical Data Review Requirements
PT-QA-019	Records Information Management
PT-QA-021	Laboratory Quality Control Program

Document No.	Title
PT-QA-022	Equipment Maintenance
PT-QA-024	Subsampling
PT-QA-026	Container Accuracy Verification – Gravimetric
PT-QA-031	Internal Chain of Custody
PT-SR-001	Sample Receipt & Login
PT-SR-002	Bottle Order Preparation and Shipping
PT-WC-001	Determination of Total and Total Volatile Solids in Waters and Wastes (Methods EPA160.4 and SM 2540B & 2540E)
PT-WC-002	Color, Method 110.2
PT-WC-003	Alkalinity, SM Method 2320B
PT-WC-004	Total Hardness (mg/L as CaCO3) by Method SM 2340C; and Hardness by Calculation SM 2340B
PT-WC-005	Turbidity by Method 180.1
PT-WC-007	Nitrate/Nitrite-N EPA Method 353.2
PT-WC-008	Acid Volatile Sulfides (AVS) and Simultaneously Extracted Metals (SEM) in Sediment
PT-WC-009	Performance Checks on Spectronic 21 and Model 1001 Spectro-Photometers
PT-WC-010	Total Sulfide as Acid Soluble Sulfide, Method 9030B/9034, Standard Method 20th Ed. 4500S-2-F
PT-WC-013	Specific Conductance by 120.1, 2510B, and 9050A
PT-WC-014	Nitrogen, Ammonia (Automated), Method 350.1
PT-WC-015	Chromium, Hexavalent (Colorimetric) by SM3500-Cr-B, SW846 3060A/7196
PT-WC-016	Biochemical Oxygen Demand (BOD) and Carbonaceous Biochemical Oxygen Demand (CBOD) by Dissolved Oxygen Probe - SM5210B
PT-WC-017	Total Organic Carbon (TOC) and Total Inorganic Carbon (TIC), Methods SM 5310C and SW-846 9060/9060A
PT-WC-018	Cyanide – Semi-Automated, Pyridine-Barbituric Acid For Total and Amenable, Cyanide in Water (Methods 335.4) and Soil Analyses (Method 9012A/9012B)
PT-WC-020	Percent Moisture, Ash, Organic Matter and Total Solids in Soil Samples - SM 2540G and ASTM D297-84
PT-WC-021	Flash Point by Pensky-Martens Closed Tester, SW-846 Method 1010A and ASTM D93-08
PT-WC-022	Ignitability of Solids for Waste Characterization EPA SW-846 Chapter 7, Section 7.1
PT-WC-023	Chemical Oxygen Demand, Low Level, Method 410.4
PT-WC-025	n-hexane extractable material (HEM) in Sludge, Sediment and Soil samples - 9071B

Document No.	Title
PT-WC-026	PH Electrometric by SM 4500 H+B and SW-846 Methods: 9045C/D and 9040B/C
PT-WC-027	Salinity by Calculation, Electrical Conductivity Method SM 2520B
PT-WC-028	Hexane Extractable Material (HEM; Oil and Grease) and Silica Gel Treated Hexane Extractable Material (SGT-HEM; TPH), Method 1664A/1664B and 9070A
PT-WC-029	Available Cyanide by Ligand Exchange and Flow Injection Analysis (FIA) Method 1677
PT-WC-031	Cyanide Extraction Procedure for Solids and Oils, SW-846 Method 9013
PT-WC-032	Total Organic Carbon Analysis for Solid Matrices by Walkley Black
PT-WC-033	DI-Leachate Procedure for Solids (1 Hour Routine DI Leachate Procedure)
PT-WC-034	Paint Filter Liquids Test, SW-846 Method 9095B
PT-WC-035	Acidity of Water and Waste Water, SM Method 2310B
PT-WC-036	Flash Point of Liquids by Setaflash (Small Scale) Closed-Cup Apparatus, SW-846 Method 1020B and ASTM Standard D 3278-96
PT-WC-037	Oxidation Reduction Potential, SM 2580B (20th Ed)
PT-WC-038	Phenolics (Automated), Method 420.1/420.2, SW-846 9065/9066
PT-WC-039	Screening Apparent Specific Gravity and Bulk Density of Waste - Method: ASTM D 5057-90
PT-WC-040	Anion Surfactants as MBAS, Standard Methods 5540C
PT-WC-041	Compatibility of Screening Analysis of Waste, Method: ASTM D5058 Test Method C – Water Compatibility
PT-WC-042	Acid Titration of Samples for Bechtel Bettis (NaOH Solution for Caustic and Na2CO3 Concentration), Bechtel-Bettis SOP - WAPD-MT(CAC)-2141, Revision 0
PT-WC-043	Determination of Total and Volatile Suspended Solids in Waters and Wastes - EPA 160.4 and SM 2540D & 2540E
PT-WC-044	Determination of Settleable Solids in Water SM 2540F
PT-WC-045	Determination of Total Dissolved and Volatile Dissolved Solids in Water and Wastes, SM 2540C & 2540E
PT-WC-046	ASTM 18-Hour Leaching Procedure

Note: The SOPs are subject to change, refer to PT-QA-WI-002 for current list of SOPs and revision numbers.

1. SCOPE AND APPLICATION

1.1. The distillation procedure described in this method is designed for the determination of total sulfides in aqueous, solid waste materials, or effluents in conjunction with method 9030B/9034.

1.2. This procedure measures total sulfide, which is usually defined as the acid-soluble fraction of a waste. If, however, the client has previous knowledge of the waste and is concerned about both soluble sulfides such as H_2S, and metals sulfides, such as CuS and SnS_2, then total sulfide is defined as the combination of both acid-soluble and acid-insoluble fractions. For wastes where only metals sulfides are suspected to be present, only the acid-insoluble fraction needs to be performed.

1.3. Total Sulfide includes dissolved H_2S and HS^-, as well as acid-soluble metallic sulfides present in suspended matter. The S^{2-} is negligible, amounting to less than 0.5% of the dissolved sulfide at pH 12, less than 0.05% at pH 11 etc. Copper and silver sulfides are so insoluble that they do not respond in ordinary sulfide determinations; they can be ignored for most practical purposes.

1.4. This method is not applicable to oil or multiphasic sample or samples not amenable to the distillation procedure. Such samples must be forwarded to a lab that can perform the analysis by Method 9031.

1.5. Methods 9030B and 9034 are suitable for measuring sulfide concentrations in samples, which contain between 0.2 mg/kg to 50 mg/kg of sulfide.

1.6. Method 9030B is not applicable for distilling reactive sulfide. Method 9034 may be used to quantify the concentration of sulfide from the reactivity test.

1.7. The titration procedure is suitable for the measurement of Sulfide at concentrations in waters above 3 mg/L. This concentration is used as the reporting limit.

1.8. Unionized Hydrogen Sulfide (SM 4500-S^{2-}F) can be calculated from the concentration of dissolved sulfide, the sample pH and the practical ionization constant of H_2S.

1.9. Any modifications to this procedure must be approved by the QA department or the Laboratory or Technical Director and documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1. For acid-soluble sulfide samples by method 9030B/9034, separation of sulfide from the sample matrix is accomplished by the addition of sulfuric acid to the sample. The sample is heated to 70℃ in a sealed distillation a pparatus for 90 minutes. The distillation apparatus is continuously purged with nitrogen gas. Any hydrogen sulfide (HS) that is formed is carried by the nitrogen stream into gas scrubbing bottles containing a solution of zinc acetate where the hydrogen sulfide precipitates as zinc sulfide.

2.2. For acid-insoluble sulfide samples, separation of sulfide from the sample matrix is accomplished by suspending the sample in hydrochloric acid by vigorous agitation. The acidified sample is distilled at 100^{o}C under a stream of nitrogen. Hydrogen sulfide gas is released from the sample and collected in gas scrubbing bottles containing zinc(II) and a strong buffer. Zinc sulfide precipitates.

2.3. The sulfide in the zinc sulfide precipitate is quantified titrimetrically by Method 9034. Excess iodine is added to the sample, which oxidizes the sulfide to sulfur under acidic conditions. The excess iodine is back titrated with sodium thiosulfate. Samples are distilled according to method 9030B to remove interferences.

2.4. For method SM 4500-S^{2-}F, excess iodine is added to a sample that is treated with zinc acetate to produce zinc sulfide. The iodine oxidizes the sulfide to sulfur under acidic conditions. The excess iodine is back titrated with sodium thiosulfate. Samples are pre-treated according to method SM 4500-S^{2-}C to remove interferences.

3. DEFINITIONS

3.1. TALS – TestAmerica Laboratory Information Management System

3.2. NCM - Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3. Refer to the glossary in the Laboratory Quality Manual (PT-QA-M-001), current version for additional definitions.

4. INTERFERENCES

4.1. Aqueous samples must be taken with minimum aeration to avoid volatilization of sulfide, which oxidizes sulfide to sulfur compounds that are not detected. Use deoxygenated, deionized water and reagents. Avoid aerating the sample to minimize the exposure of the sample to atmospheric oxygen.

4.2. Carbonates in the sample may affect the distillation by causing excessive gassing when acid is added.

4.3. Reduced sulfur compounds, such as sulfite and hydrosulfite, will decompose in acid and form sulfur dioxide. This gas may carry over to the zinc acetate solutions and subsequently react with iodine during the titration, thus causing a positive bias to the

results. This method shows no sensitivity to sulfite up to 10 mg/kg of sulfite in the sample.

4.4. The iodometric method suffers interference from reducing substances that react with iodine, including thiosulfate, sulfite, and various organic compounds.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001), and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2. Safety Note: If you forget, and the samples have been heated once on the distillation block, DO NOT add reagents, let the samples completely cool first and redistill.

5.3. Sodium Sulfide will form Hydrogen Sulfide (HS) gas if combined with water moisture or strong acids. Inhalation of H_2S gas can cause headache, dizziness, nausea, unconsciousness and potentially death.

5.4. The following is a list of the materials used in this method, which have a serious or significant hazard rating. NOTE: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material (1)	Hazards	Exposure Limit (2)	Signs and Symptoms of Exposure
Hydrochloric Acid	Corrosive Poison	5 ppm - Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failures, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Iodine	Poison Corrosive Oxidizer	0.1 ppm - Ceiling	Vapors severely irritating and can burn the mucous membranes and respiratory tract. Liquid contact may cause blistering burns, irritation, and pain. Vapors may be severely irritating to the skin. Vapors are severely irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Sodium Sulfide	Corrosive	10ppm-TWA 15ppm-STEL	Will form Hydrogen Sulfide (HS) gas if combined with strong acids. Inhalation of HS gas may be fatal. Symptoms include

			painful conjunctivitis, headache, nausea, dizziness, coughing, and, in extreme cases, pulmonary edema and possible death. Irritant. Contact with skin can produce serious caustic burns and painful inflammation and possible destruction of tissue. Eye contact can cause inflammation, tearing and pain. Severe contact can cause destruction of tissue.
Material (1)	**Hazards**	**Exposure Limit (2)**	**Signs and Symptoms of Exposure**
Sulfuric Acid	Corrosive Oxidizer Dehydrator Poison Carcinogen	1 mg/m^3 - TWA	Inhalation produces damaging effects on the mucous membranes and upper respiratory tract. Symptoms may include irritation of the nose and throat and labored breathing. Symptoms of redness, pain, and severe burns can occur. Contact can cause blurred vision, redness, pain, and severe tissue burns. Can cause blindness.
(1) – Always add acid to water to prevent violent reactions.			
(2) – Exposure limit refers to the OSHA regulatory exposure limit.			

5.5. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.6. Exposure to chemicals must be maintained as low as reasonably achievable, therefore, unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.7. VITON gloves may be worn when halogenated solvents are used for extraction or sample preparation, nitrile gloves may be used when other solvents are handled. [Note: VITON is readily degraded by acetone; all solvents will readily pass through disposable latex rubber gloves.]

5.8. The preparation of standards and reagents will be conducted in a fume hood with the sash closed as far as the operation will permit.

5.9. All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or the EH&S coordinator.

5.10. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1. Boiling tube
6.2. Inlet adapter
6.3. Dropping funnel
6.4. Gas inlet
6.5. Impinged bubbler
6.6. Bubbler vessels
6.7. WestClips®, size 24/40
6.8. Gas line “T” connector
6.9. Class A Volumetric flasks, pipettes, and burettes
6.10. High purity nitrogen gas
6.11. Regulator
6.12. Easy Midi distillation heating block
6.13. 100mL disposable flasks
6.14. 50mL burette
6.15. Glass microfiber filter

7. REAGENTS AND STANDARDS

Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee of Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.1. Reagent water - All references to water in this method refer to laboratory reagent water or deionized water

7.2. Hydrochloric acid – concentrated, purchased

7.2.1 Hydrochloric acid (9.8N): Slowly add 817mL of concentrated HCL to 100mL reagent water in a 1L volumetric flask and dilute to volume with reagent water.

7.2.2 Hydrochloric acid (6N): Slowly add 500mL of concentrated HCl to 400mL reagent water in a 1L volumetric flask and dilute to volume with reagent water.

7.3. Sulfuric acid (H_2SO_4) – concentrated, purchased

7.3.1. 1:4 Sulfuric acid – slowly add 25mL concentrated acid to 50mL laboratory reagent water in a 100mL volumetric flask and bring to volume with reagent water. THIS SOLUTION WILL BE VERY HOT.

7.4. Zinc acetate dehydrate – $Zn(O_2CCH_3)_2 \bullet 2\ H_2O$, purchased

7.5. Sodium acetate – $Na(O_2CCH_3)$, purchased

7.6. Zinc acetate solution (0.5M) – for Acid-Soluble Sulfides: Dissolve about 110g zinc acetate dihydrate in 200mL of reagent water. Add 1mL concentrated HCL, to prevent precipitation of zinc hydroxide. Dilute to 1L. Store at room temperature. This solution expires 1 year after preparation, not to exceed the expiration of the parent salt.

7.7. Zinc acetate/sodium acetate buffer – for Acid-Insoluble Sulfides: Dissolve 100g sodium acetate and 11g zinc acetate in 800ml reagent water. Add 1mL concentrated HCL, to prevent precipitation of zinc hydroxide. Dilute to 1L. Store at room temperature. This solution expires 1 year after preparation, not to exceed the expiration of the parent salts.

7.8. UHP/zero grade nitrogen gas, gas chromatographic grade, with two-stage regulator

7.9. Starch indicator (0.5%), purchased

7.10. Sodium Thiosulfate solution (0.025N), purchased with certificate of analysis.

7.10.1. If necessary, this solution may be prepared in the lab from certified ACS $Na_2S_2O_3.5H_2O$ by weighing 24.82g, diluting to 4L in reagent water and preserving with 36 mL of 1N NaOH. (NOTE: Weights/Volumes can be adjusted as long as proportionality is maintained.)

7.11. 0.025N Iodine, commercially purchased standard. This standard can also be prepared from 1N Iodine solution commercially purchased. Pipette with a class A pipette 50mL of 1N solution and diluting to 2L with reagent water.

7.12. 1000ppm Sodium sulfide spiking solution is prepared by dissolving approximately 1.8g $Na_2S\bullet 9H_2O$ in 250mL reagent water. The exact concentration of the solution must be titrometrically determined due to loss of sodium sulfide due to atmospheric oxygen and/or water vapor. (NOTE: Weights/Volumes can be adjusted as long as proportionality is maintained.) Prepare this standard fresh weekly and determine the exact concentration every day of use. Store at $4 \pm 2^{o}C$. A new TALS Reagent must be entered each day if the concentrations changes from the previously entered standard. The mass must be adjusted to match the titration determined concentration from the worksheet. (See Figure 2)

7.12.1. Secondary 1000ppm Sulfide Spiking Solution – prepared following steps in 7.12 above, with a second source of sodium sulfide.

7.13. Potassium Biiodate powder, commercially purchased

7.13.1. Standard 0.0250N Potassium Biiodate: dissolve 0.8124g potassium biiodate (dried 2 hours) in reagent grade water and dilute to 1 L.

7.14. Stannous Chloride Crystal, Dihydrate, Purchased

7.15 Anti-foaming agent, Sigma Antifoam Y-30 or similar

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

Sample container, preservation requirements and holding times are listed below.

Matrix	Sample Container	Min. Sample Size	Preservation	Holding Time	Reference
Water	Plastic or Glass	250 mL	2N Zinc acetate and 6N NaOH to pH >9, Cool > 0 to ≤ 6.0°C	7days from collection	40 CFR Part 136
Solid	Glass	4 oz amber jar	2N zinc acetate until soil is moistened Cool >0 to ≤ 6.0°C	7days from collection	40 CFR Part 136

8.1. All aqueous samples and effluents must be preserved in the field with zinc acetate and sodium hydroxide to pH > 9. Sample bottle should be filled completely, with a minimum of aeration. The treated sample is relatively stable and can be held for up to seven days. For solid samples, the surface of the solid should be covered with 2N zinc acetate until moistened. If samples are received not properly preserved, this is noted in an NCM to be included in the narrative.

8.2. Samples must be kept cooled at >0 to ≤ 6℃ and stored headspace free.

8.3. If after distillation, the distillate can not be immediately titrated it may be stored at >0 to ≤ 6℃ for up to 24 hours before final titration pro vided the 7 day holding time from sample collection is not exceeded.

9. QUALITY CONTROL

9.1. The following quality control samples are prepared with each batch of samples.

Quality Controls	Frequency	Control Limit
ICV/CCV (not distilled)	Prior to sample analysis, after every 10 titrations and at the end of the run	4500 S^{2-} F 90-110% 9034 85-115%
ICB/CCB (not distilled)	Prior to sample analysis, after every 10 titrations and at the end of the run	< RL
Method Blank (MB)	1 per preparation batch[1]	< RL

Quality Controls	Frequency	Control Limit
Laboratory Control Sample (LCS)	1 per preparation batch[1]	85-115 %
Matrix Spike (MS)[3]/MSD	1 per preparation batch[1]	75-125[2]% and 20% RPD

[1]A batch is limited to 20 samples.
[2]Statistical control limits will be developed when there is sufficient data and updated as per SOP PT-QA-021.
[3]The MS/MSD is randomly selected, unless specifically requested by a client.

9.2. Method Blank (MB): A method blank is processed using reagent grade water and all chemical reagents and procedures as the associated samples. The MB associated with distillation of soil samples uses glass, plastic or Teflon beads to simulate a solid matrix. It is used to monitor laboratory and/or reagent contamination. As a part of the QC batch it accompanies the samples through all the steps of the preparation and analytical procedure. Any treatment step performed on a sample must also be performed on the MB.

9.2.1. The ICB and CCB are reagent water only, and are not taken through the distillation step with samples. The ICB is analyzed at the beginning of the analytical batch, prior to any samples. A CCB is analyzed after every 10, or fewer, samples, and at the end of the analytical batch. For water batches analyzed without distillation, the ICB serves as the MB.

9.2.2. All blank (ICB/CCB/MB) results must be less than the reporting limit; otherwise all samples must be re-prepared and reanalyzed, unless one of the following conditions applies:

- If all associated samples are non-detect, results may be reported with the NCM “Method Blank – Report, ND”. If associated samples have concentrations that are greater than 10 times the MB concentration, results may be reported with the NCM “Method Blank – Report, 10X”.

- If reanalysis is not possible due to limited sample quantity, the PM will be notified and results will be reported flagged with a “B” qualifier and the NCM “Method Blank – Insufficient Sample”.

- If reanalysis will be outside of holding time, the PM must be notified and client instructions obtained for reporting results or reanalyzing sample. Corrective action taken must be included in the case narrative.

9.3. The exact Sodium Sulfide Spiking Standards’ concentration must be determined each day of use by titrating 1.0mL of solutions 7.12 and 7.12.1, diluted to approximately 100mL with reagent water. Titrate each stock standard, following the analytical procedure in section 10.5. Use the Sulfide Analysis Standardization Logsheet, PT-WC-

WS-011, to calculate both the true value and the mass to enter into the TALS Reagent for this true value. (See Figure 2).

NOTE: The TALS Reagent is adjusted for the titrated true value by entering the exact weight of sodium sulfide crystals that would produce the determined concentrations.

Sodium sulfide in g = determined concentration / 534

9.4. ICV and CCV are prepared in laboratory reagent water with 1.0mL of spiking solution 7.12, and the true value is determined per section 9.3. Recovery must be within ± 85-115% for method 9034 and within 90-110% for method SM 4500 S^{2-} F.

9.4.1. The ICV and CCV are not taken through the distillation step with the samples. If samples are analyzed without distillation, the ICV may serve as the LCS, and the ICV control limits must be met. ICV/CCV control limits for method 9034 are 85-115%, for SM 4500S^{2-} F, the limits are 90-110%.

9.4.2. If the ICV does not meet recovery criteria, check calculations, re-standardize the iodine solution and titrant and repeat. If a CCV does not meet criteria, reanalyze once. If the failure repeats, re-standardize the iodine solution and titrant and repeat the analysis of all samples run after the last passing CCV.

9.5. Laboratory Control Sample (LCS): The LCS is a spiked blank matrix used to monitor the accuracy of the analytical process independent of possible interference effects due to sample matrix. The LCS associated with soil samples uses glass, plastic or Teflon beads to simulate a solid matrix. Laboratory Control Sample is processed through all preparation and analytical steps with the samples. Any treatment step performed on a sample must also be performed on the LCS.

The LCS spike is 1.0mL of the secondary spiking solution 7.12.1, and the true value is determined per section 9.3. Recovery must be within ± 15% for method 9034 and ± 10% for method SM 4500 S^{2-} F.

9.5.1. If the LCS does not meet recovery criteria, all associated samples must be redistilled and reanalyzed, unless one of the following conditions applies:

- If the LCS recovery is above the control limits, and all sample results are non-detect, results may be reported using the “LCS/LCSD - %R High” NCM.
- If re-distillation/reanalysis is not possible due to limited sample quantity, the laboratory project manager will be notified to inform the client. Results shall be reported flagged with a “*” qualifier and the NCM “LCS/LCSD – Insufficient Sample”.
- If reanalysis will be outside of holding time, the client must be notified and approval from the client must be obtained for the reanalysis.

9.6. One matrix spike and matrix spike duplicate pair is required on 1 per every 20 samples in the batch. The MS is performed on a second portion, and the MSD on a third, of a sample chosen at random in the batch, unless a client specifies a sample to be used. If there is insufficient sample to perform both an MS and MSD, an MS only may be analyzed.

9.6.1. Prepare the MS and MSD by spiking 1.0mL of the spiking solution (7.12.1) into the second and third sample portion prior to distillation (or analysis if no distillation step is required).

- If the MS fails recovery criteria of 75-125%, evaluate the other batch QC results. If the LCS is acceptable and the MS/MSD are comparable and outside of QC limits, then a matrix effect is indicated. No reanalysis is required, results are reported with the NCM “MS/MSD - %R, LCS Pass”.

9.6.2. The relative percent difference (RPD) between the MS and MSD must be within ± 20 percent. If this criteria is not met, report results using the “MS/MSD/DUP - %RPD” NCM.

10. PROCEDURE

10.1. Standardization

The working iodine solution and sodium thiosulfate titrant are standardized daily, and the information is recorded in the standardization log, which is attached to the TALS batch.

10.1.1. 0.025N Sodium thiosulfate (7.10) standardization

10.1.1.1. Place 2g KI in 250mL beaker and add 100mL Super-Q water and stir. Add 10mL biiodate (7.13.1) and then 10mL 1:4 H_2SO_4 (7.3.1).

10.1.1.2. Place in the dark for 5 minutes. Dilute to 150mL (if additional volume is need to see the color change) and add starch indicator (7.9) to turn the solution black or dark blue.

10.1.1.3. Titrate with $Na_2S_2O_3$ (section 7.10) to clear endpoint.

NOTE: Once the color changes from dark to light blue, the titration to a clear endpoint must be done slowly to avoid over titrating.

10.1.1.4. Repeat the procedure two more times and average the three results. The normality of the titrant is calculated as:

$$N\ Na_2S_2O_3 = \frac{10\ mL\ biiodate \times 0.025\ N\ biiodate}{mL\ Na_2S_2O_3\ titrant}$$

10.1.2. 0.025N Iodine (7.11) standardization:

10.1.2.1. Place 20mL 0.0250N iodine in Erlenmeyer flask and dilute to approximately 100mL with reagent water. Add 2mL of 6 N HCl (7.2.2) and several drops of starch indicator (7.9).

10.1.2.2. Titrate with $Na_2S_2O_3$ (7.10) to a clear endpoint.

NOTE: Once the color changes from dark to light blue, the titration to a clear endpoint must be done slowly to avoid over titrating.

10.1.2.3. Repeat the procedure two more times and average the three results. The normality of the iodine solution is calculated as:

$$N\ I = \frac{N\ Na_2S_2O_3 \times mL\ Na_2S_2O_3\ titrant}{mL\ Iodine\ solution}$$

(See the example Standardization worksheet in Figure 2.)

10.2. General Sample Prep

10.2.1. If the sample is aqueous, shake the sample container to suspend any solids, then quickly decant the appropriate volume (50mL) of the sample to a graduated cylinder and transfer to the distillation flask. Be sure that a representative aliquot is used, or use the entire sample.

10.2.2. If the sample is aqueous but contains soft clumps of solid, break the clumps and homogenize the sample by shaking the sample vigorously in its container. Then the mixture of sample may be aliquotted to produce a mixture that is completely homogenous.

10.2.3. If the sample contains solid objects the solids must be broken manually. Clay-like solids should be cut with a spatula or scalpel in a crystallizing dish. Non-porous harder objects, for example stones or pieces of metal, are excluded from the sample portion used for analysis unless otherwise instructed by the client.

10.3. Method 9030B/9034 – Acid-Soluble Sulfides Preparation and Analysis

10.3.1. A preliminary experiment must be done on one water and one solid sample from each job in the analytical batch. If there are multiple jobs from the same project, then one sample from each sampling site may be tested and the result applied to all the samples from the same site. This preliminary experiment determines the approximate amount of sulfuric acid required to adjust a measured amount of the sample to pH less than or equal to 1. Place 50mL of water or 10.0g of solid sample in a beaker. Add reagent water if the samples are solid until the total volume is 50mL. Stir the mixture, determine and record the initial pH. Slowly add concentrated sulfuric acid until the pH is less than or equal to 1. (pH may be checked with pH paper.) Record the final pH. Record the amount of acid needed to change the pH to $\leq$ 1. Discard this preliminary sample.

CAUTION: Toxic hydrogen sulfide may be generated from the acidified sample. This operation **must** be performed in a hood and the sample left in the hood until the sample has been made alkaline or the sulfide has been destroyed.

10.3.2. Place a sample aliquot in the boiling tube. The default maximum sample size is 50mL for water matrices and 5.0g (in 45mL deionized water) for solid and sediment matrices. Place the boiling tube containing the sample in the heater block and assemble the sulfide distillation apparatus as shown in Figure 1.

NOTE: It may be necessary to add antifoaming agent to known swelling or foaming samples to prevent carry-over into the collection vessels. When

antifoam is added to samples it MUST also be added to the Method Blank and LCS.

10.3.3. Place 2.5mL of Acid-Soluble Sulfide (Zinc Acetate) scrubber solution (7.6) + 25mL reagent water in each of two bubbler vessels.

10.3.4. Place an impinged bubbler in the first (front) vessel, a fritted bubbler in the second (back) vessel, and seal them with WestClips®. The sealed vessels and impingers function as the gas scrubbers. Connect the first scrubber to the inlet adapter and place the second bubbler vessel in the bubbler vessel rack. Connect the two impingers in series using Tygon® tubing.

10.3.5. Close stopcock of side arm funnel. **Place 10 mL plus the volume of sulfuric acid calculated in step 10.3.1 in the dropping funnel (amount of acid needed to lower pH to 1 <u>plus</u> an additional 10 mL of acid).**

For example, if the volume of sulfuric acid determined in section 10.3.1 is 3 mL, then the total volume of sulfuric acid added to the dropping funnel will be 13 mL.

10.3.6. Connect a high-purity (GC grade) nitrogen gas source to the main inlet of the gas manifold of the aluminum heater block as specified in the Heater Block Operation Manual. Use a two-stage gas tank regulator and set the pressure into the gas manifold to 20psi.

10.3.7. Connect a black gas line from each gas manifold valve to a “T” connector and a tygon gas line from the “T” to each of the two gas inlets of the apparatus. One at the top of the dropping funnel and one at the inlet adapter as shown in Figure 1.

10.3.8. Purge assembled apparatus with high-purity nitrogen for 10 minutes to remove atmospheric oxygen from the apparatus and contained solutions. During purge, adjust nitrogen flow such that approximately five bubbles per second exit the base of the inlet adapter. A proper flow rate is indicated by a steady stream at the fritted bubbler.

10.3.9. Heat the distillation apparatus to 70^{O} C. Measure and Record the temperature of the hotblock during distillation in TALS LIMS by using a digital K Type thermometer or equivalent. Rotate where the thermometer is placed in the hotblock for each digestion. Set heater block temperature controls to the following settings:

RATE1: 15^{O} C/MIN RATE2: 0
TEMP1: 70^{O} C TEMP2: 70^{O} C
TIME1: >1.5HOUR TIME2: 0
TIMING CONFIGURATION: CONF1

(Set Time 1 to a period longer than 1.5 hours to prevent the second temperature program from immediately starting.)

10.3.10. Open stopcock of dropping funnel and allow all of the sulfuric acid to drip into the boiling tube at a rate of approximately 1mL/min. Continue to observe the boiling tube contents as acid is added to monitor for excessive foaming, swelling of solids, or formation of a non-homogeneous mixture that is not suspended by the bubbling action in the tube. It may be necessary to use a smaller sample aliquot under such conditions. Once dropping funnel is empty, close the stopcock quickly to ensure sulfide evolved from the sample is not lost into the funnel.

10.3.11. Start the heating cycle AFTER the acid has been added. Samples are heated for 90 minutes once the set temperature is reached.

10.3.12. After the 90 minute heating period, discontinue heating. Remove bubbler vessels. Turn off the nitrogen flow. If possible, leave the set-up sealed until ready to analyze the distillate. If not possible, remove the collection vessels carefully so as not to disturb the settled solids, seal and label separately. Store in an area where they will not be disturbed until analysis.

10.3.13. Carefully combine the gas scrubber solutions just prior to analysis by following the steps below. Do not shake the collection solutions to avoid exposure to air and subsequent loss of sulfide. Determine the concentration of acid-soluble sulfide in the zinc acetate gas scrubber solutions by using the Titrimetric-iodine method (9034) following the steps below.

10.3.14. Pipette 10 mL of standardized 0.025N iodine solution (7.11) and 2mL of 6N HCl (7.2.2) into an Erlenmeyer flask. Add approximately 30mL reagent water.

10.3.15. Pour the collection solution from the first scrubber into the Erlenmeyer flask containing the iodine solution by using a funnel with its tip placed below the iodine solution. Pour the solution from the second scrubber into the first scrubber vessel to rinse it and add it to the Erlenmeyer flask in the same manner.

10.3.16. Pipet another 5mL of 0.025N iodine solution (7.11) and 2mL of 6N HCl (7.2.2) into the second scrubber vessel. Rinse the second scrubber and impinger with the acidified iodine solution, to collect any remaining precipitate. Pour the

acidified iodine into the first scrubber and rinse the vessel and impinger. Add this to the analysis flask. Rinse any remaining iodine solution from both scrubbers with a small amount of reagent water and add this to the analysis flask. There should be no visible traces of precipitate after rinsing. Bring the final volume in the Erlenmeyer flask to approximately 100mL with reagent water.

10.3.17. If at any point in transferring the zinc acetate solution or rinsing the bottles, the amber color of the iodine disappears or fades to yellow, additional 0.025N iodine, in 5mL increments, must be added until the dark iodine color persists. This additional volume must be added to the amount from Section 10.3.14 and 10.3.16 for calculations. Record the total volume of standardized 0.025N iodine solution used.

10.3.18. Add several drops of starch indicator to turn the solution in the analysis flask black or dark blue.

10.3.19. Titrate the solution in the flask with standard 0.025N sodium thiosulfate solution (7.10). The sample will turn from black or dark blue to light blue. Continue titrating until the blue color disappears completely. Titrate the solution slowly as the color lightens to avoid overshooting the endpoint. Record the volume of titrant used, then double check that the titrated sample color does not change further by adding one more drop of sodium thiosulfate titrant. Record the first volume of titrant if the color does not change. Record the final titrant volume if it does.

10.4. Method 9034/9030B Acid Insoluble Sulfide (AIS) Preparation and Analysis

10.4.1. As the concentration of HCl during distillation must be within a narrow range for successful distillation of H_2S, the water content must be controlled. It is imperative that the final concentration of HCl in the distillation flask be about 6.5N and that the sample is mostly suspended in the fluid by the action of swirling the sample boiling tube. This is achieved by adding 10mL of reagent water, including water in the sample, 20 mL of 9.8N HCl (7.2.1), and the sample to the boiling tube. Solids which absorb water and swell will restrict fluid motion and, therefore, lower recovery will be obtained. Samples should be limited to 5 g dry weight.

10.4.2. Add 1 gram of stannous chloride (7.14) and then place the boiling tube containing the sample in the heater block and assemble the sulfide distillation apparatus as shown in **Figure 1.**

10.4.3. Place 25mL of the sodium acetate/zinc acetate buffer (7.7) in each of two bubbler vessels. Place an impinged bubbler (front) in the first vessel, a fritted

bubbler (back) in the second vessel, and seal them with size 24/40 WestClips®. The sealed vessels and impingers function as the gas scrubbers. Connect the first scrubber to the inlet adapter and place the second bubbler vessel in the bubbler vessel rack. Connect the two impingers in series using Tygon® tubing.

10.4.4. Close stopcock of side arm funnel, then add 20 mL of 9.8 N HCl (7.2.1).

10.4.5. Connect a high-purity (GC grade) nitrogen gas source to the main inlet of the gas manifold of the aluminum heater block as specified in the Heater Block Operation Manual. Use a two-stage gas tank regulator and set the pressure into the gas manifold to 20psi.

10.4.6. Connect a black gas line from each gas manifold valve to a “T” connector and a tygon gas line from the “T” to each of the two gas inlets of the apparatus. One at the top of the dropping funnel and one at the inlet adapter as shown in Figure 1.

10.4.7. Purge assembled apparatus with high-purity nitrogen for 10 minutes to remove atmospheric oxygen from the apparatus and contained solutions. During purge, adjust nitrogen flow such that approximately five bubbles per second exit the base of the inlet adapter. A proper flow rate is indicated by a vigorous foaming action at the fritted bubbler.

10.4.8. Heat the distillation apparatus to 100℃. Measure and Record the temperature of the hotblock during distillation in TALS LIMS by using a digital K Type thermometer or equivalent. Rotate where the thermometer is placed in the hotblock for each digestion. Set heater block temperature controls to the following settings:

RATE1: 15℃/MIN	RATE2: 0
TEMP1: 100℃	TEMP2: 100℃
TIME1: 1.5 HOUR	TIME2: 0
TIMING CONFIGURATION: CONF1	

10.4.9. Open stopcock of dropping funnel and allow all of the hydrochloric acid to drip into the boiling tube at a rate of approximately 1mL/min. Continue to observe the boiling tube contents as acid is added to monitor for excessive foaming, swelling of solids, or formation of a non-homogeneous mixture that is not suspended by the bubbling action in the tube. It may be necessary to use a smaller sample aliquot under such conditions. Once dropping funnel is empty, close the stopcock to ensure sample is not lost into the funnel. It may also be necessary to add antifoam to known swelling solids and waters.

10.4.10. After the 90 minute heating period, discontinue heating. Remove bubbler vessels. Turn off the nitrogen flow. If possible, leave the set-up sealed until ready to analyze the distillate. If not possible, remove the collection vessels carefully, seal and label separately.

10.4.11. Determine the concentration of acid-soluble sulfide in the sodium acetate/zinc acetate gas scrubber solutions following steps 10.3.13 through 10.3.19 above, using 10mL of 6N HCl (7.2.2) in step 10.3.14 rather than 2mL.

10.5. Method SM 4500-S^{2-}F

10.5.1. Add 10 mL of a 0.025N iodine solution (7.11) into a 125mL Erlenmeyer flask or beaker. The iodine solution is bright orange/brown in color.

10.5.2. Add approximately 2ml of 6N HCl (7.2.2).

10.5.3. Pipette 50 mL of sample into the flask, keeping the tip of the pipette below the surface of the sample. (If necessary, add reagent water until there is sufficient solution in the flask to see the color change at the end of the titration.) Add several drops of starch indicator to turn the solution black/dark blue.

NOTE: When preparing a matrix spike, spike the sample portion first, then transfer it to the flask containing the acidified iodine solution.

10.5.4. If the iodine color disappears, re-prepare the sample with additional iodine solution in 10.5.1. If re-preparation is not possible due to limit sample volume, add more iodine solution in 10mL increments until the color remains. Record the total volume of standard iodine added.

10.5.5. Back-titrate with 0.0250 N sodium thiosulfate (7.10), Titrate slowly as the blue color fades so as not to overshoot the end point. The endpoint is reached when the blue color disappears completely. Record the volume of titrant used.

11 CALCULATIONS / DATA REDUCTION

11.1. Calculate the amount of Sulfide in the sample:

$$\text{Sulfide (mg/L)} = \frac{[(A \times B) - (C \times D)] \times 16000}{\text{mL of sample}}$$

Where:

A = mL of iodine solution

B = N of iodine solution

C = mL of $Na_2S_2O_3$ solution

D = N of $Na_2S_2O_3$ solution

11.2. Un-ionized Hydrogen Sulfide as S^{2-} (mg/L) = J x Conc. of dissolved sulfide (mg/L)

Where:

J - the proportion of dissolved sulfide present as H_2S as determined by sample pH – pK' from Figure 3

pK' - the logarithm of the practical ionization constant for hydrogen sulfide at a given conductivity and temperature from Figure 4.

11.3. Duplicate sample (Relative Percent Difference):

%RPD = 100 x | A - B | / [(A+B)/2]

Where:

A - Original sample concentration

B - Duplicate sample concentration

11.4. Spike percent recovery:

$$Theoretical\ Spike\ Conc. = \frac{\left(\begin{matrix}Spike\\Conc.\end{matrix}\right) \times \left(\begin{matrix}Vol.\ of\\Spike\ Added\end{matrix}\right)}{Final\ Vol.\ Spiked}$$

$$\%\ \mathrm{Recovery} = \frac{(Spiked\ Sample\ Conc.) - Sample\ \mathrm{Result}}{Theoretical\ Spike\ Conc.} \times 100$$

12. METHOD PERFORMANCE

12.1. The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2. Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3. Method Detection Limit (MDL) for Titrimetric Procedures - The detection limit for titrimetric procedures can be defined by the smallest increment of titrant that can be measured during a titration to cause a chemical change. The detection limit is calculated based on the titrant concentration, the sample size, and the minimum volume of titrant that can be measured. Method Blank performance may be used to evaluate the validity of the quantitation limit.

13. POLLUTION CONTROL

13.1. It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention."

14. WASTE MANAGEMENT

14.1. Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are found in the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

14.2. The following waste streams are produced when this method is carried out:

- Acidic waste generated by sample titration - This waste is collected in a waste container identified as "Acid Waste", Waste #33. This waste is neutralized to a final pH between 6 and 9 and discharged down into a lab sink.
- Unused sample distillate - This waste is collected in a waste container identified as "Acid Waste", Waste #33. This waste is neutralized to a final pH between 6 and 9 and discharged down into a lab sink.

16. METHOD MODIFICATIONS

16.1. Method 9030B, section 7.1.2.3 requires 37% formaldehyde solution to be added to the collection scrubber solutions as a treatment to prevent interference from sulfite or hydrosulfite in the solid sample. The addition of formaldehyde interferes with and slows the response of the reaction during the titration analysis significantly, leading to over-titration of distilled samples. Per section 3.2 of method 9030B, the sulfite/hydrosulfite does not interfere at concentrations <10mg/kg. For this reason, the formaldehyde solution has been removed from this procedure.

SOP Title: Total Organic Carbon (TOC) and Total Inorganic Carbon (TIC)
Amendment Number: 1

Effective Date of Amendment:
Append this form to the front of the SOP copy.

CONTROLLED DISTRIBUTION	
COPY # :	**001**
ISSUED TO :	**Pittsburgh SOP Directory**

The following SOP change is in effect as of the stated date. *This form will remain attached to the referenced SOP until such a time that the SOP is updated, approved, and redistributed, at which time it will become part of the historical SOP record.*

1. Briefly explain the reason for the update: 40 CFR Part 136 Update of Reference Year

2. Category for SOP Change:

☒ Typographical Corrections (Non-Technical) – Retraining Not Required.

☐ Typographical Corrections (Technical- define below) – Retraining is required.

☐ Procedural Changes (Define Below) – Retraining Required.

3. Summary of Procedure Change (circle to indicate if there are attachments to this form: No / Yes: # pages attached = ___)

15.2 Standard Methods for the Examination of Water and Wastewater, Method 5310C, 2000, editorial revision 2011, 2014

Does this change result in a Method Modification? Yes (No)
If yes, please explain below.

Any method modification will be incorporated into section 16 of the SOP at the next revision.

THIS UNPUBLISHED WORK BY EUROFINS TESTAMERICA IS PROTECTED BY STATE AND FEDERAL LAW OF THE UNITED STATES. IF PUBLICATION OF THIS WORK SHOULD OCCUR THE FOLLOWING NOTICE SHALL APPLY:

©COPYRIGHT 2020 TESTAMERICA LABORATORIES, INC. d/b/a EUROFINS TESTAMERICA ALL RIGHTS RESERVED.

1. SCOPE AND APPLICATION

1.1 The purpose of this SOP is to provide a procedure for the determination of Total Organic Carbon (TOC) or Total Inorganic Carbon (TIC) in waters and similar matrices. This SOP is based on SW-846 Method 9060A and Standard Methods 5310C.

1.2 The working linear range is 1 mg/L to 100 mg/L on the Aurora 1030 instrument. For soils the sample must undergo a leaching process prior to analysis, such as ASTM Leach. Sediment samples undergo elutriate generation prior to analysis. The reporting limit is 1 mg/L.

1.3 On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department or the Laboratory or Technical Director and documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1 Organic carbon is converted to carbon dioxide (CO_2) using chemical oxidation. The CO_2 is then measured by an infrared detector. The amount of CO_2 in a sample is directly proportional to the concentration of carbonaceous material in the sample.

3. DEFINITIONS

3.1 TALS – TestAmerica Laboratory Information Management System

3.2 NCM – Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3 Refer to the glossary in the Pittsburgh Laboratory Quality Assurance Manual, PT-QA-M-001, for other common laboratory terms.

4. INTERFERENCES

4.1 Contaminants in solvents, reagents, glassware, and other processing apparatus that lead to discrete artifacts may cause method interferences. All of these materials must be routinely demonstrated to be free from interferences under conditions of the analysis by running laboratory method blanks as described in the Quality Control section. Specific selection of reagents may be required to avoid introduction of contaminants.

4.2 Carbonate and bicarbonate interfere but are eliminated by the acidification and purging step of the instrument.

5. SAFETY

5.1 Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2 The auto sampler has a probe that is sharp; use caution not to stick yourself.

5.3 The Sodium Persulfate is a strong oxidizer. Avoid contact with combustible materials, organic materials, strong reducing agents, and excess heat.

5.4 The following is a list of the materials used in this method, which have a serious or significant hazard rating. NOTE: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material (1)	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Sulfuric Acid	Corrosive Oxidizer Dehydra-dator	1 mg/m^3	This material will cause burns if comes into contact with the skin or eyes. Inhalation of vapors will cause irritation of the nasal and respiratory system.
Phosphoric Acid	Corrosive	3 mg/M^3 PEL 1ppm STEL	Inhalation is not an expected hazard unless misted or heated to high temperatures. May cause redness, pain, and severe skin burns. May cause redness, pain, blurred vision, eye burns, and permanent eye damage.
Sodium Persulfate	Oxidizer Corrosive	0.1 mg/M^3-TWA as Persulfates	Causes irritation to the respiratory tract. Symptoms may include sore throat, shortness of breath, inflammation of nasal passages, coughing, and wheezing. Causes severe irritation or burns to the skin and eyes. Symptoms include redness, itching, pain and burns. May cause allergic skin reactions. Can cause eye damage.
1 – Always add acid to water to prevent violent reactions.			
2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.5 Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have become contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.6 Exposure to chemicals must be maintained as low as reasonably achievable, therefore, unless they are known to be non-hazardous, all samples must be opened, transferred, and prepared in a fume hood or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.7 The preparation of standards and reagents will be conducted in a fume hood with the sash closed as far as the operation will permit.

5.8 All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 OI Corporation Model 1030 TOC Analyzer, with 1088 vial multisampler
6.2 Nitrogen gas and regulator
6.3 Class A Volumetric flasks, various sizes
6.4 Class A Volumetric pipettes, various sizes
6.5 Vials: 40mL Amber glass with stir bars
6.6 Class A Graduated cylinders, various sizes
6.7 pH strips, wide range
6.8 Top loading balance capable of weighing to ± 0.01g
6.9 Automatic Re-pipetter

7. REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard.

Reagent grade chemicals must be used, unless otherwise indicated. If a certificate of analysis is not available, or the purity of a reagent or standard is questionable, analyze the reagent/standard

prior to using for the analysis of any client samples. Document the purity check in the TALS Reagent module with the entry for the reagent/standard.

7.1 Sodium Persulfate

7.1.1 Sodium Persulfate Solution: Add 100g sodium persulfate ($Na_2S_2O_8$) to a 1L volumetric flask and dilute to 1L final volume with reagent water. This solution is given a 6 month expiration date.

7.2 Phosphoric Acid, concentrated

7.2.1 Phosphoric Acid Solution: Carefully add 59mL concentrated phosphoric acid (H_3PO_4) to 900mL of reagent water in a 1L volumetric flask. Dilute to 1L final volume with reagent water. This solution is given a 6 month expiration date.

7.3 Sulfuric Acid, concentrated

7.4 TOC Primary Stock Standard, 1000ppm: This is a commercially purchased, certified standard. Follow the manufacturer's expiration date and storage requirements.

7.5 TOC Secondary Stock Standard, 1000ppm: This certified standard is commercially purchased from a different source than the primary stock. The manufacturer's expiration date and storage requirements are used.

7.5.1 If necessary, a 1000ppm TOC stock can be prepared as follows: Dilute 1.06g KHP (potassium acid phthalate) to volume in a 500mL volumetric flask. KHP is oven dried overnight at 180°C and stored in a dessicator for at least an hour before use.

7.6 TOC Calibration Standards: Prepare the calibration standards listed below from the primary stock standard (7.4). Prepare standards fresh daily for calibration use.

Concentration (mg/L)	Stock Volume (mL)	Stock Concentration (mg/L)	Final Volume (mL)
100	10	1000	100
50	5	1000	100
25	2.5	1000	100
10	1	1000	100
1	0.1	1000	100

7.7 Initial Calibration Verification (ICV) – This is a second source standard analyzed as part of initial calibration verification. A 40 mg/L standard is prepared by transferring 4 ml of the secondary stock (7.5) to a 100 ml volumetric flask and diluting to volume with reagent grade water. Prepare this standard fresh daily.

7.8 Continuing Calibration Verification (CCV): Prepare a 10mg/L verification standard by adding 2.0mL of the secondary stock standard (7.5) to a 200mL volumetric flask and diluting to volume. Prepare this standard fresh daily.

7.9 Laboratory Control Sample (LCS): Prepare a 20 mg/L standard by adding 4 mL of the primary stock standard (7.4) to a 200 ml volumetric flask and diluting to volume with reagent grade water. Prepare this standard fresh daily.

7.10 Matrix Spike/Matrix Spike Duplicate: Add 400µL of the secondary stock standard (7.5) to 40 mL of sample for a final concentration of 10 mg/L. (Spike concentration may be varied as appropriate to the native sample concentrations expected.)

7.11 TIC stock standard, 1000 mg/L: This is purchased commercially from the same vendor with different lot numbers for the primary and secondary source standards. If necessary it may also be prepared as follows: Prepare by adding 3.5g Na_2HCO_3 (sodium bicarbonate) to a 1L flask. Dilute to volume with reagent water. Keep tightly stoppered. Do not acidify.

7.11.1 TIC Calibration Standards: Prepare in the same manner as the TOC calibration standards (7.6) using the TIC primary stock standard (7.11). Prepare standards fresh daily as needed.

7.11.2 TIC Verification Standard (CCV): Prepare in the same manner as the TOC verification standard (7.8) using the TIC secondary stock standard (7.11). Prepare standard fresh daily.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

Listed below are the holding times and the references that include preservation requirements.

Matrix	Sample Container	Minimum Sample Size	Preservation	Holding Time
Water	Amber Glass VOA Vial	40 mL	pH < 2 with Sulfuric acid; Cool >0.0˚C but ≤ 6.0°C	28 days from collection

9. QUALITY CONTROL

The following quality control samples are prepared with each batch of samples.

Quality Controls	Frequency	Control Limit
ICV	After the ICAL	90-110%
ICB	After the ICV	< RL (9060A) <½ RL (SM5310C)
MB	1 per preparation batch[1]	< RL (9060A) <½ RL (SM5310C)
LCS	1 per preparation batch[1]	85-115%[2]
LCSD	If insufficient sample provided for an MS/MSD	85-115%[2]; 20% RSD
MS/MSD[3]	1 per preparation batch[1] (SM5310C) Every 10 samples (9060A)	75-125%; 20% RSD
CCV	Every 10 samples	90-110%
CCB	Every 10 samples	< RL (9060A) <½ RL (SM5310C)
RLV	Quarterly (SM5310C)	50-150%

[1]A batch is limited to 20 samples.
[2]Statistical control limits may be developed per SOP PT-QA-021, but must be 85-115% or tighter.
[3]The sample used for MS/MSD pair or Duplicate are randomly selected, unless specifically requested by a client.

9.1 The initial and continuing calibration requirements are listed in section 10.1 below. If the initial calibration, or initial calibration verification fails to meet criteria, prepare fresh standards and repeat calibration. If a continuing calibration check standard or blank fails to meet criteria, repeat the analysis once. If the failure repeats, prepare and analyze a fresh calibration curve and repeat the analysis of all samples analyzed after the last passing calibration check.

9.2 One Method Blank (MB) must be analyzed along with each batch of 20 or fewer samples. The method blank matrix is laboratory reagent water. If samples are filtered by the laboratory for Dissolved Organic Carbon analysis, a MB must be filtered and analyzed along with the samples.

9.2.1 The average (reported) Method Blank results must be less than the RL for method 9060A, and less than ½ the RL for method 5310C. Sample results associated with MB's that have hits above the MDL shall be reported with "B" qualifiers. If the MB has a hit above the RL (or ½ the RL for method 5310C), all associated samples shall be reanalyzed unless one of the following situations exists:

- If the target analyte is not detected above the RL in client samples, the data may be reported with qualifiers and using the "Method Blank – Report, ND" NCM.

- If the sample concentration is greater than 10 times the MB concentration, results may be reported with qualification and using the "Method Blank – Report, 10X" NCM.
- If neither of the above criteria are met and reanalysis is not possible due to limited sample volume, the sample data must be qualified. These results must be reported using the "Method Blank – Insufficient Sample" NCM.
- If reanalysis cannot occur for another reason, the client must be contacted and their response documented in the case narrative of the report.

NOTE: If method 9060A is used and the individual results as well as the average are reported, each individual injection must meet the MB criteria above.

9.3 Laboratory Control Sample (LCS) – One LCS is analyzed along with each batch of 20 or fewer samples, prepared according to section 7.9 above. The average (reported) LCS matrix is the same as for the MB. LCS recovery must be within 85-115%.

9.3.1 If recovery is outside the control limits, re-inject the standard once. If failure repeats, all associated sample must be reanalyzed unless one of the following situations exists:

- If LCS recovery is greater than 115% and the sample results are < RL, the data may be reported with qualification and using the "LCS/LCSD - %R High" NCM.
- If the above criteria are not met and reanalysis is not possible due to limited sample volume, the sample data must be qualified. These results must be reported using the "LCS/LCSD – Insufficient Sample" NCM.
- If reanalysis cannot occur for another reason, the client must be contacted and their response documented in the case narrative of the report.

NOTE: If method 9060A is used and the individual results as well as the average are reported, each individual injection must meet the LCS criteria above.

9.4 One sample per every 10 (for method 9060A) or 20 (for method 5310C) is also used for matrix spike and matrix spike duplicate analysis. The sample is spiked with a known amount of organic carbon per section 7.10 above. Percent recovery of the spike must be within 75-125%, and the %RPD for the pair must be $\leq$20%.

9.4.1 If the MS or MSD recovery is outside acceptance criteria, and the LCS recovery was within criteria, it is possible that the matrix of the sample contained an interference. Results may be reported with proper qualification using the MS/MSD - %R, LCS Pass" NCM.

- If the native analyte concentration in the MS/MSD exceeds 4x the spike level for that analyte, the recovery data are reported with a "4" qualifier in TALS LIMS.

9.4.2 If there is insufficient sample for MS/MSD, a LCS and LCSD may be prepared and analyzed. The recovery for LCS/LCSD must be ± 15 % and the RPD must be within ± 20%. If an LCSD is necessary, document the lack of sufficient volume to perform an MS/MSD using the "MS/MSD – Insufficient volume" NCM.

9.4.3 Samples identified as field blanks cannot be used for MS/MSD analysis.

9.5 Semiannually, the inorganic purging efficiency of the instrument must be checked by analyzing a second aliquot of the LCS, spiked with the Inorganic Carbon spike. Recovery of this TIC spiked sample and the batch LCS must agree within 10%RPD.

9.5.1 If inorganic carbon carry-over is evident in the spiked sample, adjust sample containers, volume, purge gas flow rate and/or purge time to obtain complete removal of inorganic carbon. Any changes made will be noted in the instrument maintenance log and will be a permanent change to the procedure.

9.6 A Reporting Limit Verification Standard must be analyzed on at least a quarterly basis for method 5310C. This standard is prepared from either the primary or secondary stock standard at a concentration 1-2 times the reporting limit and is analyzed in duplicate. The average result must be within 50-150% of the true value.

9.6.1 If recovery of the RLV is outside control limits, prepare a fresh standard and reanalyze. If the failure repeats, re-evaluate the reporting limit with a fresh calibration curve and a single day, 7-point MDL study.

10. PROCEDURE

10.1 Calibration

10.1.1 Initial setup

Constant Settings	
STD Mass	6.76ug C
Sample Volume	2.4mL
Acid Volume	1.0mL
Oxidant Volume	1.5mL

10.1.2 Adjust the nitrogen to 50-60 psi using the flow valve on the tank. The gauge should always be set at 50-60 psi when the instrument is not in use. (NOTE: The pressure reading on the instrument should read 20 psi when the tank pressure is between 50-60 psi.)

10.1.3 If the main valve reads < 200 psi, the tank should be changed. Do not allow the tank to go empty.

10.1.4 Remove the reagent bottles and fill with appropriate reagents (phosphoric acid solution and sodium persulfate). Do not fill bottles completely full; leave a small amount of air space. Loosely reconnect caps (and tubing), and replace the bottles into the instrument.

10.1.5 Calibrate the instrument at least every 6 months, or more often as needed when CCVs or CCBs fail to meet acceptance criteria, or when other problems are encountered. Calibrate using blank and minimum five calibration standards.

10.1.6 Choose “sequences” from the “databases” menu option, open up the calibration template.

10.1.7 Confirm all information.

10.1.8 Analyze an ICV/ICB immediately after the curve. ICV is from a second source, which is separate source from the curve.

10.1.9 Save the file using the current date as the filename.

10.1.10 Evaluate the data. The instrument uses the equation y = mx + b to calculate the linear 1st order calibration curve, where $r^2 \geq 0.995$. The correlation coefficient of the original curve must be $r^2 \geq 0.995$ or recalibration is required.

- Calculate the %Error for each calibration standard read back against the plotted curve. The %E for each point above the lowest concentration must be $\leq$ 20%. The %E for the lowest point must be $\leq$ 50%.

10.1.11 ICV/CCV (Initial &Continuing Calibration): The run is checked at the beginning (ICV – separate source from the curve), after every ten environmental samples (CCV – same source as ICV), and at the end of the run of the same species (TOC or TIC) using a midrange CCV made from a secondary source (Section 7.8 or 7.11.2) to verify continued linearity. A reported CCV value cannot vary from the original curve by more than ± 10% or recalibration is required.

- If CCV recovery is greater than 110% and the sample results are below the RL, the data may be reported with qualification and an NCM specifying the

CCV, its recovery and the <RL samples being reported. Repeated CCV failure will require a new calibration curve to be analyzed

NOTE: If method 9060A is used and the individual results as well as the average are reported, each individual injection must meet the CCV criteria above.

10.1.12 System cleanliness is checked every ten environmental samples and at the end of the run using a Continuing Calibration Blank (CCB). A reported CCB value cannot contain the analyte of interest above the reporting limit (9060A) or ½ reporting limit (SM5310C), or recalibration is required.

- If the target analyte is not detected above the RL in client samples, the data may be reported with qualifiers and NCM specifying the CCB above the RL (or ½ RL) and the associated non-detect samples reported.
- If the sample concentration is greater than 10 times the CCB concentration, results may be reported with qualification and an NCM specifying the CCB, its concentration, and the associated >10x samples reported.

  NOTE: If method 9060A is used and the individual results as well as the average are reported, each individual injection must meet the CCB criteria above.

10.1.13 All prepared standards are logged into the reagent module of TALS. All standards are assigned a unique number for identification.

10.2 Sample Preparation

10.2.1 The TOC samples, which come from the field in containers ready for analysis, are sparged by the instrument prior to TOC analysis to remove inorganic carbons that may be present. Samples requiring both TOC & TIC are received as two separate samples that are analyzed separately.

10.2.2 The instrument has analytical modes for TIC, TOC & TC analysis. Analysis after sparging is calculated by the instrument as TOC. Unsparged analysis is calculated as TC. The difference between the two results is calculated as TIC. All calculations are performed by the instrument software program based on calibration curves.

10.2.3 All sample preparation and analysis information will be documented in TALS. Raw data will be scanned and attached to the appropriate TALS batch for inclusion in the report.

10.2.4 Sample size is selected in the instrument set-up and is the same for all sample, calibration, and QC injections. The samples containing particulates will be stirred with a magnetic stirrer. The needle depth can be adjusted if necessary.

10.2.5 Samples and associated QC (i.e. Blanks, LCS, MS/MSD, ICV and CCV's) analyzed according to SM5310C will be analyzed in replicate until the injection of consecutive measurements obtained are reproducible to within ± 10% RPD.

10.2.5.1 For samples outside of ± 10% RPD criteria, the laboratory will perform up to 4 sample injections, taking the most consistent results and initiate a non-conformance indicating that the results are not within criteria due to the nature of the sample matrix. If for any reason the laboratory is not provided with enough sample to perform the analysis in replicate a notation will be made in the case narrative.

10.2.6 Samples and associated QC (i.e. Blanks, LCS, MS, ICV and CCVs) analyzed according to SW-846 Method 9060A will be analyzed in quadruplicate. Both the average and the range will be reported. Quadruplicate can mean 4 injections from the same vial or 2 injections each from 2 vials of the same sample or 1 injection each from 4 vials of the same sample depending on how the client performs the sampling process. If for any reason the laboratory is not provided with enough sample to perform the analysis in quadruplicate a notation will be made in the case narrative.

10.2.7 CCB/CCV's are analyzed per 10 samples, not injections, for both Method 5310C and 9060A.

10.2.8 The pH of TOC samples will be taken after analysis and documented in the appropriate field in the TALS Batch Worksheet. An NCM will be generated for any sample found to have a pH of > 2 so that this information can be pulled into the job-specific Case Narrative.

10.2.9 See the manufacturer's instructions for an instrument-troubleshooting guide and maintenance requirements.

11. CALCULATIONS / DATA REDUCTION

11.1 Total Organic Carbon, mg/L = Instrument Value x Dilution

Where replicate measurements are performed:

TOC, mg/L = average of the 4 instrument values* x dilution

* The four values will be considered to have an acceptable level of consistency, if each of the values lies within ± 35% of the mean. If analysis of any replicate exceeds the 35%, reanalysis will be performed and the findings narrated.

11.2 MS/MSD % Recovery = ((observed spike-sample conc.)/true spike)x100

11.3 Duplicate Sample (Relative Percent Difference):

$$RPD = \frac{|X_1 - X_2|}{\left(\frac{X_1 + X_2}{2}\right)} \text{ x } 100\%$$

Where:
X_1 = Original Result
X_2 = Duplicate

11.4 LCS Percent Recovery:

$$\text{LCS \% Recovery} = \left(\frac{\text{Observed Conc. in LCS}}{\text{True LCS Conc.}}\right) \text{ x } 100\%$$

11.5 Calculation of TIC

TIC = TC – TOC

Where:

TIC = Total Inorganic Carbon

TC = Total Carbon

TOC = Total Organic Carbon

Note: the calculation for TC, TOC and TIC is a function of the instrument's analytical software.

11.6 All instrument data is uploaded into TALS. Raw data is attached to the TALS Batch as a pdf.

12. METHOD PERFORMANCE

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2 Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual and SOP PT-QA-001, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3 Method Detection Limit Study – A Method Detection Limit (MDL) study, as described in Eurofins TestAmerica corporate Detection Limits SOP (CA-Q-S-006), must be performed initially and any time a significant change is made to the analytical system. The MDL must be evaluated at least every 12 months.

13. POLLUTION CONTROL

13.1 It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

14. WASTE MANAGEMENT

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.1.1 Acidic waste from the auto-analyzer. (This waste is collected in a waste container identified as "Acid Waste", Waste #33. This waste is neutralized to a final pH between 6 and 9 and discharged down into a lab sink.

18.14 Changes to current revision

SOP section	Change from	Change to	Reason
1.3	Removed text referring to QA Manual	Added SOP Checklist text on modications	SOP Checklist Format
7	Removed "Reagent grade" from individual reagents entries	Added blanket Reagent Grade chemicals statement	clarification
9.2.1, 9.3, 10.1.11, 10.1.12		Added: average(reported) to results and NOTE that individual must pass if 9060A reporting individual and average	clarification

9.5	Check for inorganic carbon removal per batch	Check for inorganic carbon to semiannual to be performed on an aliquot of LCS	Update
10.1.2	50 psi	50-60 psi Added a NOTE that the instrument should read 20 psi based on the 50-60psi reading on the tank	Clarification
10.1.11		Added if CCV fails high and samples are ND, samples may be reported	Clarification
10.1.12		Added if CCB fails and samples are ND or >10x the CCB concentration, samples may be reported	Clarification
12.3	MDLs per QA Manual	MDLs per corporate SOP CA-Q-S-006	Correction
15.15		Added reference for CA-Q-S-006	Clarification

SOP # with Revision: PT-WC-018 Rev. 21
SOP Title: Total Cyanide Distillation and Analysis, Semi-Automated Colorimetry

ISSUED TO :	**Pittsburgh SOP Directory**

The following SOP change is in effect as of the stated date. *This form will remain attached to the referenced SOP until such a time that the SOP is updated, approved, and redistributed, at which time it will become part of the historical SOP record.*

1. Briefly explain the reason for the update: 40 CFR Part 136 Update of Reference Year

2. Category for SOP Change:

☒ Typographical Corrections (Non-Technical) – Retraining Not Required.

☐ Typographical Corrections (Technical- define below) – Retraining is required.

☐ Procedural Changes (Define Below) – Retraining Required.

3. Summary of Procedure Change (circle to indicate if there are attachments to this form: No / Yes: # pages attached = ___)

Standard Methods for the Examination of Water and Waste Water, Method 4500-CN-C, Total Cyanide after Distillation and E, Colorimetric Method, 1999, editorial revision 2011, 2016

Does this change result in a Method Modification? Yes (No)
If yes, please explain below.

Any method modification will be incorporated into section 16 of the SOP at the next revision.

8-13-21
8-16-21

Approval Signature/Date: Technical

Amanda L Gulla 08/12/21

Approval Signature/Date: QA Manager or Designee

Title: Total Cyanide Distillation and Analysis, Semi-Automated Colorimetry

Methods: EPA Method 335.4, SM4500-CN C/E, SW-846 9010C, 9012B and 9014 - Discrete

Approvals (Signature/Date):

4/6/2020	4/6/2020
Roseann Ruyechan Date	Steve Jackson Date
Inorganics Department Manager	Regional Safety Coordinator
3/25/2020	4/1/2020
Virginia Zusman Date	Deborah L. Lowe Date
Quality Assurance Manager	Laboratory Director

1. SCOPE AND APPLICATION

1.1 This method is applicable to the determination of Total Cyanide in waters, solids, tissues and wipes using a Seal AQ2 Discrete Autoanalyzer/Spectrophotometer. It is based on EPA Method 335.4, SW846 Methods 9010C, 9012B, and 9014, and SM4500-CN C & E.

1.2 The reporting limit is 0.010 mg/L for waters, 0.25 mg/kg for solids and tissues and 0.50 ug/wipe for wipes.

1.3 On occasion clients may request slight modifications to this SOP. Any modification to this procedure must be approved by the QA department of the Laboratory or Technical Director, and documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1 For Total Cyanide: Cyanide, as HCN, is released from cyanide complexes by distilling/refluxing the sample with strong acid and absorbed in a sodium hydroxide solution.

2.2 The sodium hydroxide solution is analyzed colorimetrically on an autoanalyzer using the pyridine-barbituric acid method. The color is read at 575 nm.

3. DEFINITIONS

3.1 TALS – Test America Laboratory Information Management System

3.2 NCM – Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3 Refer to the glossary in the Laboratory Quality Manual (PT-QA-M-001) for additional definitions.

4. INTERFERENCES

4.1 Nitrates and nitrites may be a positive interference at concentrations greater than 10mg/L, but are eliminated by the addition of sulfamic acid to all samples and QC during distillation.

4.2 Oxidizing agents such as chlorine decompose most cyanides and can lead to low biased results. The presence of residual chlorine should be checked for and treated at

the time of collection. Samples are checked again prior to distillation. Chlorine interference can be removed by drop-wise addition of sodium arsenite or ascorbic acid crystals to the sample until there is no reaction to KI-starch paper.

4.3 Sulfide in the samples interferes with color formation during analysis and must be removed prior to distillation. Sulfides are removed by the addition of cadmium carbonate until there is no reaction to lead acetate paper.

5. SAFETY

5.1 Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure involves hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

Note: This method is designed to generate Hydrogen Cyanide (HCN) gas. Inhalation of CN gas can cause irritation, dizziness, nausea, unconsciousness and potentially death. Always perform the distillation under a fume hood, and ensure the hood is operating properly when in use.

5.2 Do not add reagents to heated samples. If samples have been heated prior to adding distillation reagents, turn off the heating block, allow the samples to completely cool first, and begin the distillation again.

5.3 Latex, vinyl, Nitrile or similar gloves may be used when handling samples, standards and reagents.

5.4 Ensure cooling water is turned on to the distillation unit. Otherwise the samples may boil over and come into contact with the heating block.

5.5 If samples are identified with cyanide concentrations equal to or greater than 200 mg/L, immediately notify the department manager and personnel responsible for hazardous waste shipping. Those samples must be identified as extremely hazardous for other analysts and must receive special attention during disposal.

5.6 The following is a list of the materials used in this method, which have a serious or significant hazard rating. This list may not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in

the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Potassium Cyanide	Poison Irritant	5 mg/m3, TWA	Very hazardous in case of skin contact (permeator), of ingestion, of inhalation. Hazardous in case of skin contact (irritant), of eye contact (irritant). Corrosive to eyes and skin. The amount of tissue damage depends on length of contact. Eye contact can result in corneal damage or blindness. Skin contact can produce inflammation and blistering. Inhalation of dust will produce irritation to gastro-intestinal or respiratory tract, characterized by burning, sneezing and coughing. Severe over-exposure can produce lung damage, choking, unconsciousness or death. Repeated exposure to a highly toxic material may produce general deterioration of health by an accumulation in one or many human organs.
Pyridine	Flammable Irritant	5 ppm-TWA	Inhalation causes severe irritation to the respiratory tract. Symptoms of overexposure include headache, dizziness, nausea, and shortness of breath. Causes severe irritation possibly burns, to the skin. Symptoms include redness and severe pain. Absorption through the skin may occur, resulting in toxic effects similar to inhalation. May act as a photosensitizer. Vapors cause eye irritation. Splashes cause severe irritation, possible corneal burns and eye damage.
Silver Nitrate	Poison Corrosive Oxidizer	0.01 mg/m3 TWA	Symptoms of inhalation may include burning sensation, coughing, wheezing, laryngitis, shortness of breath, headache, nausea and vomiting. Symptoms of skin contact include redness, pain, and severe burns; eye contact causes blurred vision, redness, pain, severe tissue burns and eye damage.
Sodium Hydroxide	Corrosive	2 mg/m3-Ceiling	Severe irritant. Effects from inhalation of dust or mist vary from mild irritation to serious damage of the upper respiratory tract, depending on severity of exposure. Symptoms may include sneezing, sore throat or runny nose. Contact with skin can cause irritation or severe burns and scarring with greater exposures. Causes irritation of eyes, and with greater exposures it can cause burns that may result in permanent impairment of vision, even blindness.

Material	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Sulfuric Acid (1)	Corrosive Oxidizer Dehydra-dator	1 mg/m^3	This material will cause burns if comes into contact with the skin or eyes. Inhalation of vapors will cause irritation of the nasal and respiratory system.
Zinc Acetate	Irritant	None Listed	Symptoms of skin or eye contact include redness, itching and pain.
Cadmium Carbonate	Carcinogen Poison Irritant	0.01 mg/m^3 - TWA	Toxic if inhaled or swallowed. May cause skin, eye and respiratory tract irritation.
Sulfamic Acid	Corrosive Irritant	None Listed	Extremely destructive to tissues of the mucous membranes and upper respiratory tract. Symptoms may include burning sensation, coughing, wheezing, laryngitis, shortness of breath, headache, nausea and vomiting. May cause pulmonary edema, a medical emergency. Pulmonary edema may be delayed up to 48 hours. Swallowing can cause severe burns of the mouth, throat and stomach leading to death. Can cause sore throat, vomiting and diarrhea. Skin contact can result in redness, pain and severe burns. Eye contact can cause blurred vision, redness, pain, severe tissue burns and eye damage.
Sodium arsenite	Poison Reproduc-tive Hazard Carcinogen	None listed	Symptoms of inhalation include respiratory tract irritation. Causes skin irritation, and may be fatal if absorbed through skin.
Ascorbic acid	Not classified	OSHA PEL TWA (Total Dust) 15 mg/m3	Most important symptoms and effects, both acute and delayed:Irritation, Nausea,Headache, Shortness of breath.
Chloramine-T	Corrisive	None Listed	Causes burns by all exposure routes. May cause allergy or asthma symptoms or breathing difficulties if inhaled. Product is a corrosive material. Use of gastric lavage or emesis is contra indicated. Possible perforation of stomach or esophagus should be investigated: Ingestion causes severe swelling, severe damage to the delicate tissue and danger of perforation: Symptoms of allergic reaction may include rash, itching, swelling, trouble breathing, tingling of the hands and feet, dizziness, light-headedness, chest pain, muscle pain.
Barbituric Acid		None Listed	There are no signs or symptoms of exposure.
1 – Always add acid to water to prevent violent reactions.			
2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.7 Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.8 Exposure to chemicals must be maintained as low as reasonably achievable. Therefore, unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made. Preparation of sodium hydroxide solutions produces considerable amounts of heat. Use plastic containers to mix this solution if possible. If glass containers are used, they must be free of any cracks or irregularities.

5.9 The preparation of standards and reagents will be conducted in a fume hood with the sash closed as far as the operation will permit. Ensure cooling water is turned on to the distillation unit. Otherwise the samples may boil over and come into contact with the heating plates.

5.10 All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 Cyanide Distillation Apparatus – Midi “Easy-Dist System” Westco/Unity

6.2 SimpleDist® Micro Cyanide Distillation System, heating block and distillation tube units – Environmental Express

Note: The volume markings on the SimpleDist® collection tubes must be verified for each lot following the procedure in SOP PT-QA-026 prior to use.

6.3 Vacuum Pump with trap

6.4 Class A Graduated Cylinders: Various sizes

6.5 Class A Volumetric Flasks: Various Sizes

6.6 Automated Pipette

6.7 Balance: Accurate to 0.1 mg

6.8 Seal AQ2 Discrete Spectrophotometer/Autoanalyzer and AQ2 analytical software, detector wavelength set to 575nm

6.9 Lead Acetate Indicator Paper

6.10 Potassium Iodide (KI) – Starch Indicator Paper

6.11 pH paper

6.12 Disposable 120 mL containers

6.13 Glass/plastic/Teflon beads

7. REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard.

Many of the reagents and standards listed below may be purchased commercially as an alternative to preparing them in-house. Purchased standards and reagents must come with a certificate of analysis. Reagents and chemicals purchased must be reagent grade, or better if specified below. Standards and reagents will use the manufacturer's assigned expiration date unless one is not provided. If not provided, the same expiration period will be assigned as listed for the lab-prepared reagent, using the received date in place of the preparation date.

NOTE: Any reagents and/or spiking solutions stored in the refrigerator should be warmed to room temperature prior to use.

7.1 Use deionized (DI) or reagent grade water (18 mohm) to prepare all solutions.

7.2 Distillation Reagents – Midi distillation (50mL sample)

7.2.1 Sodium Hydroxide (0.25 N): Purchased with certification of analysis

- Alternately, this solution may be prepared in the laboratory: In a 1L volumetric flask, dissolve 10.0g NaOH in approximately 900mL reagent-grade water. Dilute to volume with reagent grade water and mix thoroughly. Store in a plastic bottle, at room temperature.

- If purchased, follow manufacturer's storage and expiration instructions. If prepared in the lab, the solution expires 1 year from the preparation date, not to exceed the expiration of the parent solution or solid.

- Discard solution if a precipitate is seen.

7.2.2 Concentrated Sulfuric Acid, H_2SO_4

7.2.3 Magnesium Chloride hexahydrate ($MgCl_2 \bullet 6H_2O$)

7.2.4 Magnesium Chloride Solution, 510g/L - this solution is purchased

- Alternately, this solution may be prepared in the laboratory: Dissolve 510g of $MgCl\bullet 6H_2O$ in DI water and dilute to 1 L in a volumetric flask. Store at room temperature. If prepared in the laboratory, this solution expires 1 year from preparation date, not to exceed the expiration of the parent solid.

7.2.5 Sulfamic Acid, crystals

7.2.6 Glacial Acetic Acid, CH_3CO_2H

7.2.7 Powdered Cadmium Carbonate

7.2.8 Sodium Arsenite Solution (0.1N): Dissolve 3.2g $NaAsO_2$ in 250mL DI water. Store at room temperature. This solution expires 1 year from preparation date, not to exceed the expiration of the parent solid.

7.2.9 Ascorbic acid crystals

7.3 Distillation Reagents – SimpleDist® Method (6mL sample)

7.3.1 Sodium Hydroxide (0.25 N): See 7.2.1 above

7.3.2 Sulfamic Acid Solution: Dissolve 12g sulfamic acid (7.2.5) in 100 mL reagent water. Store in plastic bottle at room temperature. This solution expires 1 month after preparation.

7.3.3 Sulfuric Acid/Magnesium Chloride Solution – Add 277 mL of reagent water to a 500 mL volumetric flask. Add 80.5 g magnesium chloride hexahydrate (7.2.3) and stir until completely dissolved. Slowly add 189 mL concentrated sulfuric acid (7.2.2) with stirring. CAUTION: This addition will produce significant heat from the solution. This should be performed in a hood as toxic fumes may be produced. Allow solution to cool to room temperature and dilute to 500 mL.

Store in glass or plastic container at room temperature. This solution expires 1 year after preparation.

7.4 Analytical Reagents

7.4.1 Sodium Hydroxide (0.25N): See 7.2.1 above.

7.4.2 Phosphate Buffer 1.0 M: In a 1L volumetric flask, dissolve 138g KH_2PO_4 in approximately 800mL reagent-grade water. Dilute to volume with reagent grade water and mix thoroughly. Store at >0 to $\leq 6^oC$. This solution expires 6 months from the preparation date, not to exceed the expiration of the parent solid. Discard if solution becomes cloudy, or mold growth is seen.

7.4.3 Chloramine-T Solution: Dissolve 1.0g of chloramine-T hydrate in reagent-grade water. Dilute to 100mL volume with reagent grade water and mix thoroughly. Store at >0 to $\leq 6^oC$. Prepare fresh weekly.

7.4.4 Pyridine - Barbituric Acid Reagent: In the fume hood, place 15g barbituric acid in a 1L volumetric flask and add approximately 250 mL of reagent grade water, rinsing down the sides of the flask to wet the barbituric acid. Add 75 mL pyridine (C_5H_5N) with stirring. Add 15 mL concentrated hydrochloric acid (12 M HCl) slowly, and mix until the barbituric acid is dissolved. Dilute to volume with reagent grade water and mix thoroughly. Store at >0 to $\leq 6^oC$ in a dark bottle. This solution expires 6 months from the preparation date, not to exceed the expiration of any parent components.

Note: Barbituric Acid is difficult to obtain, and must be ordered 6 months in advance. Request a new supply before you run out. (This chemical can only be purchased from MG Scientific – Avantor, JT Baker B654-05.)

7.4.5 Silver Nitrate solution (0.0192N), purchased with certificate of analysis. Follow manufacturer's storage and expiration requirements.

7.4.6 Rhodanine Indicator, purchased - Follow manufacturer's storage and expiration requirements.

7.5 Standards Preparation:

7.5.1 Cyanide Stock Standard (1000 mg/L CN): This is purchased commercially with certificate of analysis. This standard should be standardized weekly as follows:

7.5.1.1 Dissolve approximately 0.2g NaOH in 25mL of DI water in beaker 1.

7.5.1.2 Add 5.0mL of CN Stock to beaker 2 and dilute to 50mL with DI water. Repeat with second source standard (7.5.2) in beaker 3.

7.5.1.3 Add 10 drops of Rhodanine Indicator to each beaker.

7.5.1.4 Titrate solutions with 0.0192N Silver Nitrate to a salmon-pink endpoint.

7.5.1.5 Record the titration information in the CN Stock Logbook.

7.5.1.6 ((A-B) x 1000mg/L) / C = True Value of Stock, where:

A = mL $AgNO_3$ to titrate stock
B = mL $AgNO_3$ to titrate blank
C = mL stock analyzed (5.0)

7.5.2 Second Source (Independent) Cyanide Stock (1000mg/L CN): This solution is purchased commercially from a different NIST traceable source than solution 7.5.1 and is used for verification of the calibration source (ICV).

7.5.3 Cyanide Working Solution 1 (Curve, CCV, MS/MSD) 10mg/L CN: Pipette 1mL* of the Stock Standard (7.5.1) into a 100mL volumetric flask containing 50 mL of 0.25 N NaOH. Dilute to volume with 0.25 N NaOH and mix thoroughly. Prepare fresh weekly.

7.5.3.1 *If the CN Stock (7.5.1) True Value as calculated in 7.5.1.1 – 7.5.1.5 is not 1000mg/L, adjust the volume of stock used to prepare Solution 1:

X = (10.0mg/L x 100mL) / T, where:

T = True Value of the stock as calculated (mg/L)
X = mL stock required to prepare 10mg/L solution

7.5.4 Cyanide Second Source Intermediate Solution for ICV and LCS (10mg/L CN): Prepare an intermediate standard from the second source stock (7.5.2) following the same steps as in 7.5.3 above.

7.5.5 Calibration Standards: Set of six. The standard curve may not have fewer than five standards. Calibration standards are distilled along with SimpleDist® samples. Standards are not distilled for use with the Midi distilled samples. Prepare fresh daily.

7.5.5.1 Calibration Preparation Standard: Prepare a 0.50 mg/L standard by pipetting 5.0 mL of the 10.0 mg/L working standard (7.5.3) into a 100 mL

volumetric flask and dilute to volume with 0.25N NaOH. This standard is prepared fresh at least every 3 days.

7.5.5.2 Manual Standard Curve for SimpleDist® samples: 0.5, 0.25, 0.1, 0.05, 0.025 and 0.01 mg/L. Using a calibrated pipette, add 6.0, 3.0, 1.2, 0.6, 0.3 and 0.12 mL of the 0.5 mg/L standard (7.5.5.1) into a SimpleDist® sample tube. Bring to 6mL volume with 0.25 N NaOH. 0.25 N NaOH is used for the 0 mg/L standard or calibration blank and ICB/CCB, and is also distilled.

7.5.5.3 Automated Calibration Curve for Midi-distilled samples: The instrument uses the 0.50 mg/L standard (7.5.5.1) to prepare the same calibration standards as listed above in 7.5.5.2.

7.5.5.4 To verify the efficiency of the distillation procedure low and high standards prepared daily from the same free cyanide source (7.5.1) as the calibration curve are distilled along with the sample batch. The recovery must be within ±10 percent of the response for the calibration standards.

- Low standard (0.05mg/L) = 5.0mL Calibration Std-0.5 (7.5.5.2)/50mL with 0.25N NaOH
- High standard (0.25mg/L) = 1.25mL Working Solution 1 (7.5.3)/50mL with 0.25N NaOH

7.5.6 ICV – Initial Calibration Verification (0.20 mg/L CN): Pipette 2.0mL of the second source 10mg/L working standard (7.5.4) into a 100mL volumetric flask. Bring to volume with 0.25 N NaOH and mix. This standard is not distilled for Midi-distilled samples. Prepare fresh every 3 days.

7.5.7 CCV - Continuing Calibration Verification (0.10mg/L CN): Add 1.0mL of 10mg/L Working Solution 1 (7.5.3) to a 100mL volumetric flask. Bring up to volume with 0.25N NaOH and mix thoroughly. This standard is not distilled for Midi-distilled samples. Prepare fresh every 3 days.

7.5.8 Complex Cyanide Stock Standard for complex LCS (1000 mg/L) – purchased commercially and prepared from a complex cyanide source, such as potassium ferrocyanide.

7.5.8.1 Intermediate Complex Cyanide Standard (10 mg/L): Pipette 1mL of the 1000 mg/L Complex Cyanide Stock Standard into a 100mL volumetric flask containing 50 mL of 0.25 N NaOH. Dilute to volume with 0.25 N NaOH and mix thoroughly.

7.5.9 Instrument blanks (ICB and CCBs) are 0.25N NaOH. Instrument blanks are not distilled.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

Table 1 –Holding Time and Preservation Requirements

Matrix	Sample Container	Minimum Sample Size	Preservation	Holding Time to Analysis	Reference
Water	Amber Glass or Plastic	500 mL	pH > 12 with NaOH, Cool > 0 to ≤ 6.0°C	14 days from collection	40 CFR Part 136
Solid	Glass, 8 oz.	250 grams	Unpreserved, Cool > 0 to ≤ 6.0℃	14 days from collection	40 CFR Part 136

9. QUALITY CONTROL

Table 2 – QA/QC Requirements and Frequency

Quality Controls	Frequency	Control Limit
Initial Calibration, minimum 5 standards and a blank	Daily	Linear regression, $r^2 \geq 0.995$, y-intercept $\leq \pm$ 1/2RL
ICV (Second Source Standard)	After the ICAL	90-110%
ICB, CCBs and MB	After ICV and CCVs	< RL for method 9012/9014 < MDL for method 335.4 < ½ RL for SM4500 CN
Continuing Calibration Verification CCV	1 per every 10 samples	90-110 %
MDLV or LOQ verification (LLOQ for metho 9014)	Quarterly to validate quantitation capability at low analyte concentration levels	±35% of True Value with ≤20% RSD between MDLV's
Low and High Distilled Standard Check	1 set per prep batch (required for 9010C)	90-110%
Laboratory Control Sample (LCS) LCS may be either free CN (from 7.4.4) Or Complex CN (7.4.8)	1 per preparation batch	90-110% (335.4 and SM4500-CN E) 85-115% (9012B and 9014) waters See sect 9.4.2 for soil LCS information
Duplicate (MD)	1/20 samples Required for SM4500CNC&E	≤ 20% RPD
Matrix Spike (MS)	1/10 samples 1/20 samples	90-110% (335.4 and SM4500-CN E) 75-125% (9012B and 9014)
Matrix Spike Duplicate (MSD)	1/20 sample	90-110% Recovery(335.4/SM4500-CN) 75-125% (9012B and 9014) ≤ 20% RPD

9.1 A Preparation Batch is 20 or fewer samples of the same matrix, distilled within the same working shift using the same reagent lots.

9.2 A Method Blank is distilled and analyzed along with each batch of 20 or fewer samples of the same matrix.

9.2.1 The MB for water batches is 0.25N NaOH.

9.2.2 The MB for solid batches must include a clean solid matrix like glass or Teflon beads. For the Midi distillation, 1 g of clean solid matrix is used, 0.2 g for the SimpleDist® method.

9.2.3 If the MB has a concentration above the reporting limit for methods 9012/9014, above the MDL for method 335.4, or above ½ the RL for method SM 4500 CN, the analyst will check calculations and instrument performance and reanalyze the MB once. If the MB is confirmed to be contaminated, one of the following corrective actions is required:

- Evaluate the sample results. If all associated samples are non-detect, results may be reported with the NCM "Method Blank – Report, ND". If associated samples have concentrations that are greater than 10 times the MB concentration, results may be reported with the NCM "Method Blank – Report, 10X".

- Samples for which neither of the above criteria apply must be redistilled and reanalyzed.

- If re-distillation/reanalysis is not possible due to limited sample quantity, the laboratory project manager will be notified to inform the client. Results shall be reported flagged with a "B" qualifier and the NCM "Method Blank – Insufficient Sample".

- If reanalysis will be outside of holding time, the client must be notified and approval from the client must be obtained for the reanalysis. If reanalysis is performed past holding time, both the initial and reanalysis results must be included in the report.

9.3 A Laboratory Control Sample is distilled and analyzed along with each batch of 20 or fewer samples of the same matrix.

9.3.1 A water batch LCS may be prepared from the free Cyanide Stock Standard (7.5.4) or from a complex cyanide source (7.5.8). For SimpleDist® distillation the LCS is prepared by adding 0.12 mL of 10mg/L intermediate standard to 6mL of 0.25N NaOH.

9.3.2 The LCS for solid matrices is a commercially purchased Standard Reference Material or certified solid QC standard. 1.0g of the solid LCS is used for the Midi distillation and 0.2g for the SimpleDist®. Recovery of a solid LCS must be within the control limits supplied with the standard by the manufacturer.

9.3.3 If LCS recovery is outside the control limits, the analyst will check calculations and instrument performance and reanalyze the LCS once. If the LCS failure is confirmed, one of the following corrective actions is required:

- Evaluate the sample results. If LCS recovery is above control limits and all associated samples are non-detect, results may be reported with the NCM "LCS/LCSD - %R High".
- Samples associated with low LCS recovery, or samples with detected CN associated with high LCS recovery must be redistilled and reanalyzed.
- If redistillation/reanalysis is not possible due to limited sample quantity, the laboratory project manager will be notified to inform the client. Results shall be reported flagged with a "*" qualifier and the NCM "LCS/LCSD – Insufficient Sample".
- If reanalysis will be outside of holding time, the client must be notified and approval from the client must be obtained for the reanalysis.

9.4 Low and high concentration free cyanide standards (7.5.5.4 - 50ppb and 250ppb prepared from the same source as the calibration standards) are distilled and analyzed along with each sample batch. These standards are to verify the distilled vs undistilled method performance, and are not matrix-matched to the samples in the batch. Corrective actions are the same as for the LCS above. A fresh calibration curve may be analyzed and the sample batch reanalyzed without re-distillation once.

9.5 If the ICV does not verify the calibration curve, check the instrument conditions and if necessary perform instrument maintenance, then analyze a new calibration curve followed by a fresh ICV.

9.6 All reported data must be bracketed by an acceptable calibration curve and a CCV, or by consecutive acceptable CCVs. If a CCV %Recovery is outside control limits, one of the following corrective actions is required:

9.6.1 Evaluate the sample results. If CCV recovery is above control limits (recoveries up to 120%) and all associated samples are non-detect, results may be reported with the NCM "CCV- %D High, Sample ND". If CCV recovery is above 120%, samples not bracketed by acceptable CCV must be reanalyzed.

9.6.2 Samples associated with low CCV recovery, or samples with detected CN associated with high CCV recovery must be reanalyzed. This applies to all samples bracketed by the failing CCV.

9.7 A Continuing Calibration Blank (ICB and CCB), which is 0.25 N NaOH will be run immediately following each ICV and CCV. All reported data must be bracketed by instrument blanks (ICB and CCBs) that show continuous clean operation of the instrument. If a CCB has a concentration above the reporting limit for methods 9012/9014, above the MDL for method 335.4, or above ½ the RL for method SM 4500CN, one of the following corrective actions is required:

9.7.1 Evaluate the sample results. If all associated samples are non-detect or samples have concentrations that are greater than 10 times the CCB concentration, results may be reported with the NCM "CCB – Outside Criteria, Samples ND or 10X".

9.7.2 Samples for which neither of the above criteria apply must be reanalyzed. This applies to all samples which the failing CCB brackets.

9.8 Lower Limit of Quantitation Check Standard (LLOQ) – For Method 9014 only, the LLOQ is the lowest point of quantitation for the laboratory. The LLOQ is verified by the analysis of a standard at the LLOQ concentration that have been taken through all distillation and analytical steps. At a minimum, the LLOQ verification is analyzed quarterly basis to validate quantitation capability at low analyte concentration levels.

9.8.1 The recovery of the LLOQ should be ± 35% of the true value and the RSD between successive LLOQ's should be ≤20%.

9.8.2 If recovery or RPD is outside the acceptance range, an MDL study must be performed and the RL (LLOQ) must be reestablished.

9.9 A matrix spike is required on one sample per every 10 in a preparation batch for EPA method 335.4, and 1 per every 20 samples for all other methods addressed by this SOP. The MS is performed on a second portion of a sample chosen at random in the batch, unless a client specifies a sample to be used.

9.9.1 For the Midi Distillation, prepare the MS by spiking 0.5mL of the 10mg/L Working Standard 1 (7.5.3) into 50mL of water sample or 1 g of soil sample. For sediment samples, add 1.0 mL of Working Standard 1 to 2 g of sample. The spike concentration is 0.10 mg/L or 5 mg/Kg.

- For SimpleDist® distillation, prepare the MS by spiking 0.12mL of the 10mg/L Working Standard 1 (7.5.3) into 6.0mL of water sample or 0.5g of

soil or sediment sample. The spike concentration is 0.20 mg/L or 1.2 mg/Kg.

9.9.2 If the MS (or the MSD) fails recovery criteria, check calculations and instrument performance, and reanalyze the failed QC once. If MS (or MSD) failure is confirmed, one of the following corrective actions is required:

- Evaluate the other batch QC results. If the LCS is acceptable and the MS/MSD are comparable and outside of QC limits, then a matrix effect is indicated. No reanalysis is required, results are reported with the NCM "MS/MSD - %R, LCS Pass".

- Evaluate the parent sample result. If the parent sample required dilution because the initial concentration of the sample is excessively high, then the MS/MSD should be run at the same dilution as the unspiked sample. The MS/MSD should never be run at a dilution greater than the associated sample as this alters the matrix of the sample and thereby makes it invalid. If the parent sample concentration is greater than 4x the spiked amount, the MS recovery cannot be accurately calculated, and the NCM "MS/MSD – High Targets" should be used.

9.10 A sample duplicate is a second portion of a sample chosen at random that is taken through the distillation and analytical steps along with the parent sample.

9.10.1 Duplicate (MD), Matrix Spike (MS), and Matrix Spike Duplicate (MSD) analyses are required for method SM4500-CN C&E.

9.10.2 For methods 335.4 and 9010C & 9012/9014 either a MD and MS set or an MS and MSD set may be analyzed along with the sample batch to meet QC criteria.

9.10.3 If the %RPD limit is exceeded, and sample and duplicate results are above 5x the reporting limit, sample and duplicate should be redistilled. If sample and duplicate results are <5x the reporting limits, results should agree within a difference of the reporting limit concentration.

10. PROCEDURE

10.1 Calibration

10.1.1 A standard curve, (prepared as in section 7.5.5) is analyzed daily on the auto analyzer for cyanide.

10.1.1.1 The calibration standards are not distilled with the Midi distillation procedure. The calibration standards are distilled with the SimpleDist® distillation procedure.

10.1.1.2 The standard curve is analyzed in order of increasing concentration.

10.1.1.3 A linear regression (1st order) calibration curve of absorbance vs concentration is plotted. The correlation coefficient must be greater than or equal to 0.995 and the absolute value of the y-intercept must be less than or equal to ± ½ the reporting limit.

10.1.1.4 Calculate the %Error for each calibration standard read back against the plotted curve. The %E for each point above the lowest concentration must be ≤ 20%. The %E for the lowest point must be ≤ 50%.

Note: Temperature of reagents and spiking solution can affect the response factor of the colorimetric determination. The reagents and standards stored in the refrigerator should be warmed to room temperature prior to use.

10.2 Distillation

10.2.1 Water samples must be checked for proper preservation and the presence of matrix interferences prior to distillation.

10.2.1.1 Check the sample pH by pouring a small portion of the sample into a disposable cup and dipping a pH test strip into it. Document the sample pH directly on the TALS Worksheet. If the sample pH is <12, notify the lab project manager that the sample was improperly preserved. Correct the pH to ≥12 in the sample by adding 1mL of 1N NaOH to a 100mL aliquot of sample, mixing and checking the pH again. Document the final pH, if adjusted, on the TALS worksheet. If adjustment was needed, apply the NCM "Preservation – pH Adjusted, pH Included" to the sample.

10.2.1.2 Samples should be checked in the field for the presence of residual chlorine or other oxidizers and pre-treated. Check samples again prior to distillation to confirm using Potassium Iodide (KI) Starch paper. Drip several drops of sample onto a KI-Starch paper strip. If the paper turns blue, it is necessary to treat the sample to remove the oxidizer prior to distillation. To a 100mL portion of sample, add 0.1N Sodium Arsenite solution (7.2.8) or 0.06g Ascorbic acid (7.2.9) slowly while stirring, until a drop of sample no longer produces a reaction with the KI-Starch paper. Document the presence or absence of

chlorine/oxidizers on the TALS Worksheet. If pretreatment is needed, document the lot of treatment used in the TALS Batch Information, and apply the NCM "Preservation – Chlorine-Pre-Treatment" to the sample. NOTE: if any samples are treated, the MB and LCS must have this treatment added as well.

10.2.1.3 Samples must be checked for the presence of sulfides prior to distillation. Drip a few drops of sample onto lead acetate test paper. If the paper darkens, the sample must be treated to remove the sulfide interference. Document the presence or absence of sulfide on the TALS Worksheet. If pretreatment is needed, document the lot of treatment used in the TALS Batch Information, and apply the NCM "Preservation – Sulfide – Pre-Treatment" to the sample. NOTE: if any samples are treated, the MB and LCS must have this treatment added as well.

- Add powdered cadmium carbonate slowly to a 75mL portion of sample with stirring. Yellow cadmium sulfide will precipitate from the sample.

- When a drop of treated sample no longer reacts with the lead acetate test strip, filter the sample through a dry filter paper into a dry beaker and take from this the sample volume to be distilled. It is not necessary to distill calibration standards if this method of pre-treatment is used.

- Solid, tissue and wipe samples are not checked for sulfides until after the distillation is complete. If sulfides are detected in the distillate, it is treated with powdered cadmium carbonate until there is no reaction to the lead acetate paper.

10.2.2 Prepare batch QC according to sections 7.5 and 9 above.

10.2.3 For water samples, pour 50mL of sample into a distillation flask for Midi distillation or 6mL into the sample tube for SimpleDist® distillation.

10.2.4 Refer to PT-QA-024 for subsampling procedures. For solids, wastes and tissues, weigh 1.0g of sample and transfer to a distillation flask and bring volume to approximately 50 mL with reagent grade water for Midi and 0.2g of sample to approximately 5mL with reagent water for SimpleDist® distillation.

- For sediments, use 2.0 g of sample for Midi or 0.5g sample for SimpleDist® and proceed as above.

- For wipe samples, add the entire wipe to the distillation flask along with any liquid present in the jar and bring to 50mL with reagent water. Wipes can only be distilled by the Midi distillation method, they cannot be prepared using the SimpleDist® procedure.

10.2.5 For MIDI distillation procedure, continue to step 10.2.6. For SimpleDist® distillation instructions, skip to section 10.2.12.

10.2.6 Add 50 mL of 0.25 N NaOH solution to the receiving flasks.

10.2.7 Assemble the cyanide distillation apparatus. Turn on the vacuum source and adjust the flow such that an even stream of air bubbles from the scrubber tube in the collection flask.

10.2.8 Through the inlet tube, add approximately 0.2g of sulfamic acid to all samples and QC. Rinse the inlet tube with a small amount of reagent water and allow the samples to mix for three minutes.

10.2.9 Add 2.5mLs of concentrated sulfuric acid. Rinse the inlet tube with a small amount of reagent water and allow the samples to mix for three minutes. Add 2.0mL magnesium chloride solution and rinse the inlet tube with a small amount of reagent grade water.

10.2.10 Turn on the cooling water. Set the Westco controller to Program 1 to begin heating. Heat the sample to boiling, adjust the vacuum on each sample to keep the air flow steady without overflowing the collection flask. The samples are distilled/refluxed for 1.5 hours after boiling begins. Be sure to adjust the airflow as necessary. After the heating period, turn off the heat and allow to cool for at least fifteen minutes. Keep the vacuum on until samples are cooled and ready for transfer.

10.2.11 Disconnect the scrubber and drain the sodium hydroxide solution from the collection flask into a 120mL disposable container. Label the container with the sample ID. Proceed to section 10.3 for analysis.

10.2.12 For the SimpleDist® procedure, set the temperature of the heating block to 120^{o}C and allow the heat to stabilize for approximately 30 minutes.

10.2.13 Add 2.0 mL of 0.25N NaOH solution to the “Measure” end of the collection tube for each sample and QC. Cap the tube with 1 membrane and cap. Ensure that the membrane is not torn and shows a visible edge all the way around the tube before adding the cap.

10.2.14 Add 6 mL of sample or QC to each sample tube.

NOTE: An ID may be marked on the tube with permanent ink, but labels cannot be placed on the sample tubes, as this will interfere with loading them in the block.

10.2.15 Add 0.10mL of sulfamic acid solution (7.3.2) and swirl gently to mix.

10.2.16 Add 0.75 mL of sulfuric acid/magnesium chloride solution (7.3.3) to THE FIRST sample tube. Immediately place the "Distill" end of a filled and capped collection tube (10.2.13) over the open end of the sample tube. Press the 2 pieces together to form a rough fit. You will not be able to hand press a tight seal.

10.2.17 Place the distillation unit in the tube press. Hold the collection tube by the break joint (indentation in the center) to give support during the sealing procedure. Firmly press the two pieces together with one motion. The collection tube should be flush with the ring around the edge of the sample tube. If the pieces are not flush, or at a visible angle, repeat the procedure with a fresh portion of sample starting at step 10.2.14.

10.2.18 Repeat until all samples and collection tubes are connected.

10.2.19 Place each assembled and sealed distillation units into the pre-heated block. Ensure that the unit is completely inserted in the block by having the ring on the "Distill" side of the tube flush against the surface of the block.

10.2.20 Distill samples for 45 minutes.

10.2.21 Heat and chemical resistant gloves must be worn for the following steps.

10.2.22 Remove ONE unit from the heating block. Immediately hold it over a disposal container and pull the sample tube off of the collection tube. This must be done quickly, or the distillate could suck back into the sample tube. If this occurs, the distillation process must be started over.

10.2.23 Dispose of the remaining sample liquid in an acid waste container.

10.2.24 Turn the collection tube so that the capped side is down, roll the collected solution around the sides of the vial to collect any condensate. Allow the tubes to cool for approximately 30 minutes, then snap the tube at the break joint.

10.2.25 Bring the distillate up to 6mL final volume with 0.25N NaOH solution. The tube may be capped with parafilm if the analysis will not be done immediately.

10.3 Automated Analysis by Seal AQ2

10.3.1 Open ASQ2 shortcut.

10.3.2 Turn instrument on using the large switch located on the back. Let the instrument warm up for at least 1 hour before analyzing samples. Make sure that the waste container is empty and the DI water container is full.

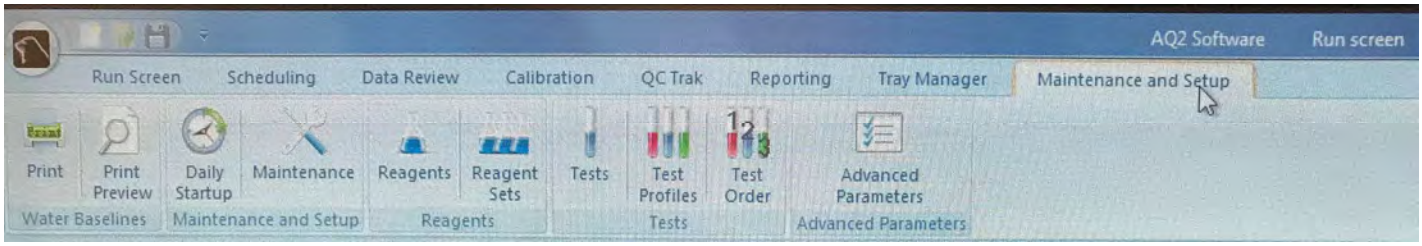
10.3.3 Add reagents to the reagent wells. Make sure the reagent wedges are full, but DO NOT over-fill. (The autosampler will stop if reagents are over-filled. In the event that the reagents are not in the reagent wheel, reagent positions can be checked in the software using the Maintenance and Setup tab, and selecting Reagent Sets.

10.3.3.1 Position 10 – 0.50 mg/L Standard (7.5.5.1) – position used for Midi distilled sample analysis only

10.3.3.2 Position 5 – Phosphate Buffer (7.4.2)

10.3.3.3 Position 6 - Chloramine-T Solution (7.4.3)

10.3.3.4 Position 7 – Pyridine-Barbituric Acid Reagent (7.4.4)



10.3.3.5 Position 8 – 0.25N NaOH solution (7.4.1) – position only used for dilutions for SimpleDist® samples, not blanks

10.3.3.6 Position 9 – 0.10mg/L CCV Standard (7.5.7) – position used for Midi distilled sample analysis only

10.3.4 Check the gold platens. If they are not already pushed in, push them in and tighten the screw knobs (front-left and back-center).

NOTE: If the gold platens are not over-tightened, they do not need to be unscrewed after every run, although it is good practice to do so.

10.3.5 Once the SEAL has been warmed up, select “Daily Start Up” from the Maintenance and Settings tab.

10.3.6 Running the Daily Start Up procedure will wash the cuvette 3times, as well as prime the syringe 10 times and run the water baselines, ensuring the SEAL is ready for daily use.

- Print the water baselines from the Maintenance and Setup tab next t the Daily Startup button.

NOTE: One of the filters should have a value of approximately 8.9. The “Dark” filter should have a value of approximately 0.003. If these numbers are not achieved, perform maintenance or flush the system and repeat.

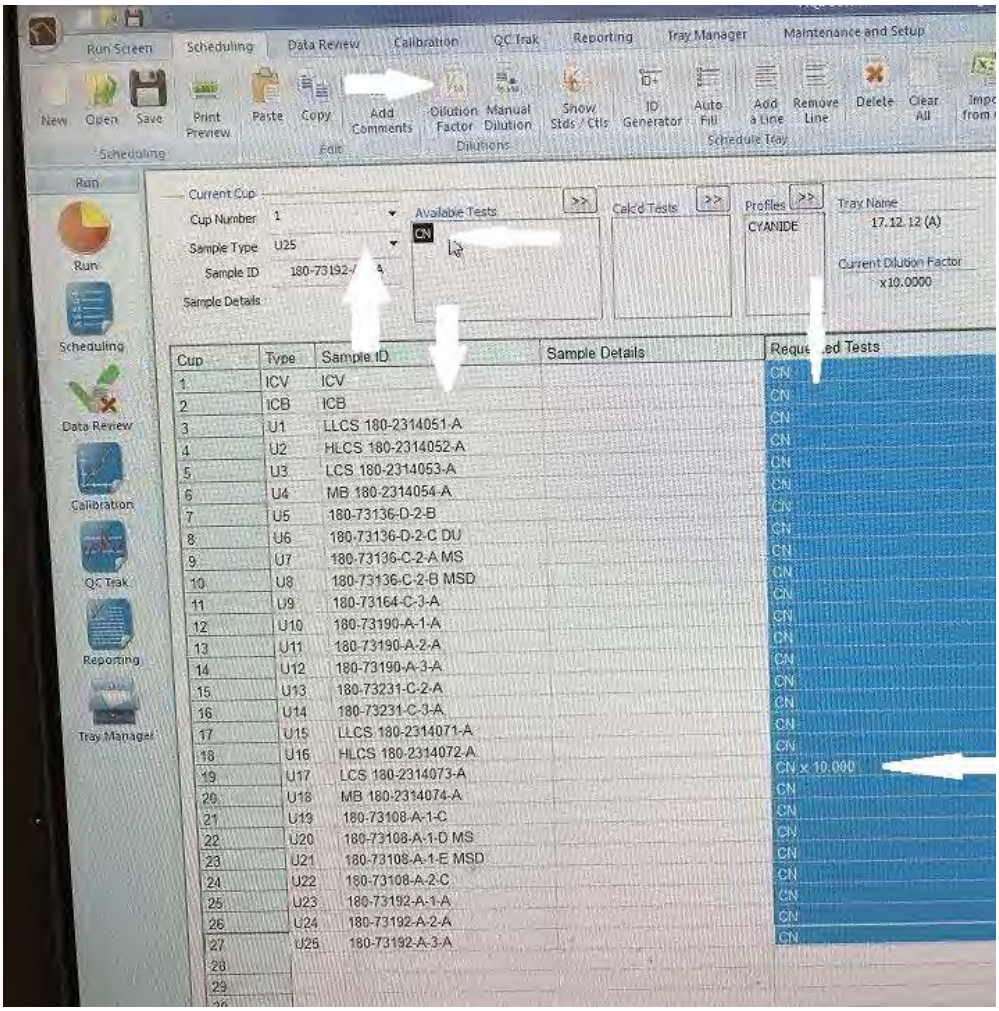
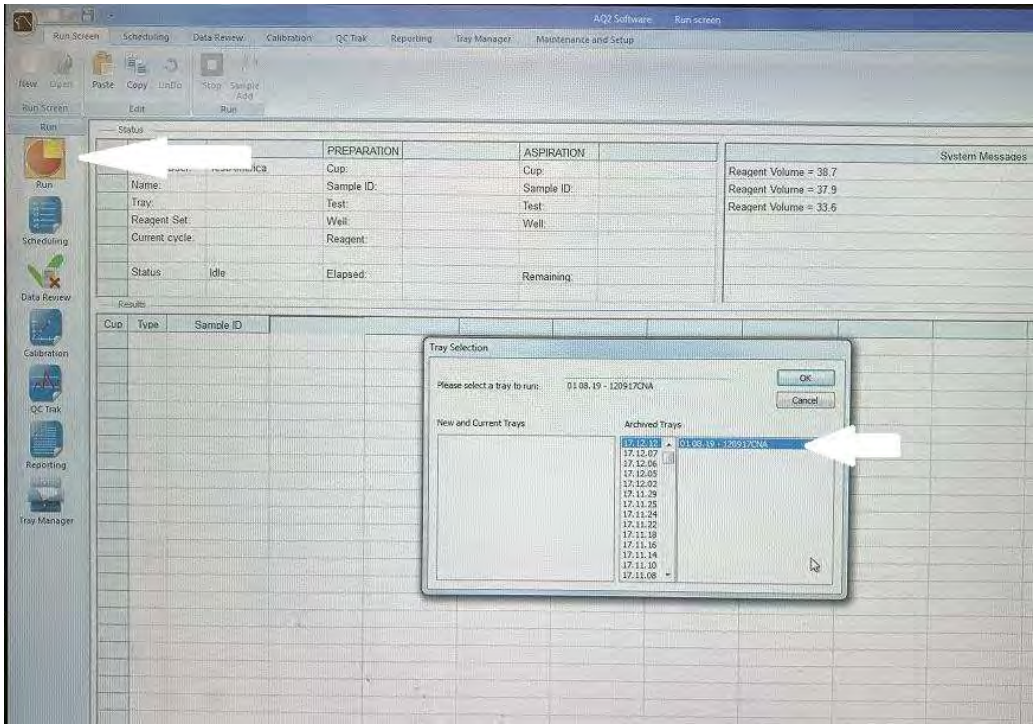
7	880nm	7.1980 v	7.1901 v
8	Dark	0.0052 v	0.0049 v



10.3.7 Click on the Scheduling icon. Choose the first "FREE" tray and select the CN reagent set. Name the schedule by using the day's date and "CAN" (or B, C, etc).

10.3.8 In the Scheduling table, highlight the first row in the Sample ID column and select ICV from the drop down menu. Move to the next row and select ICB from the drop down menu. Scan in the samples from the prep batch information sheet directly below the ICB.

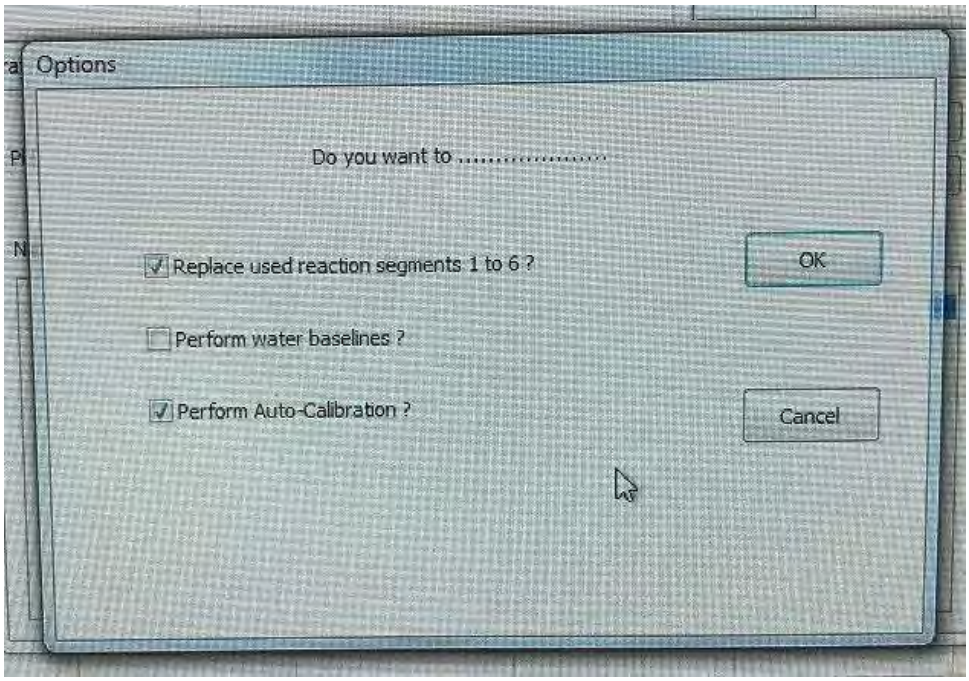
10.3.9 Highlight all entry rows and click on CN in the Available Tests box.



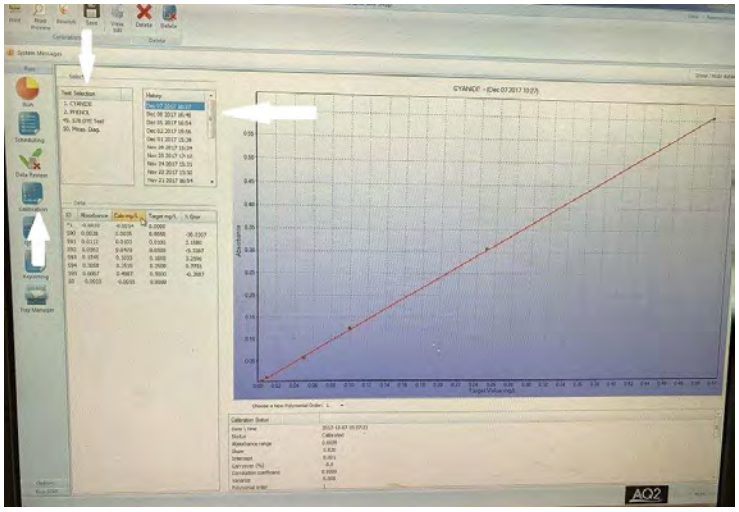
10.3.10 If a dilution is necessary, for the solid LCS for example, click on the sample in the tray. Click the Dilution Factor icon at the top of the screen and select the appropriate dilution from the menu and click OK. Click the test name under Available Tests twice to apply the dilution.

10.3.11 Save the schedule by date: <<121219CNA>>

10.3.12 Add autosampler cups to the tray according to the schedule. Using disposable transfer pipettes, add samples into the sample cups that correspond to their spot on the tray. Load the tray onto the instrument.

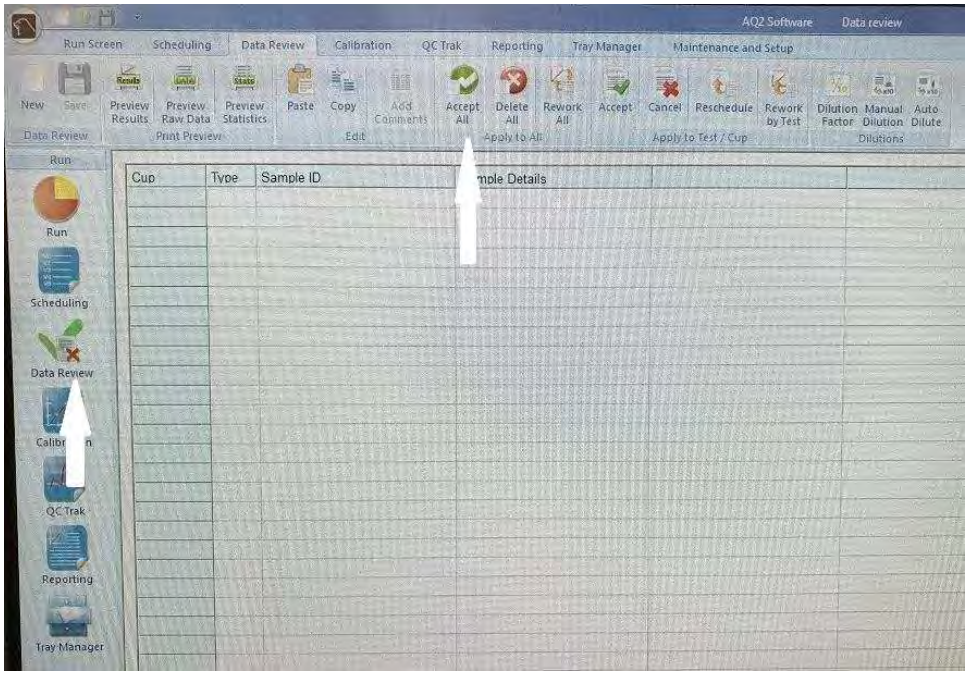


10.3.13 Click on the Run icon. Choose the schedule that was just saved, and click OK.



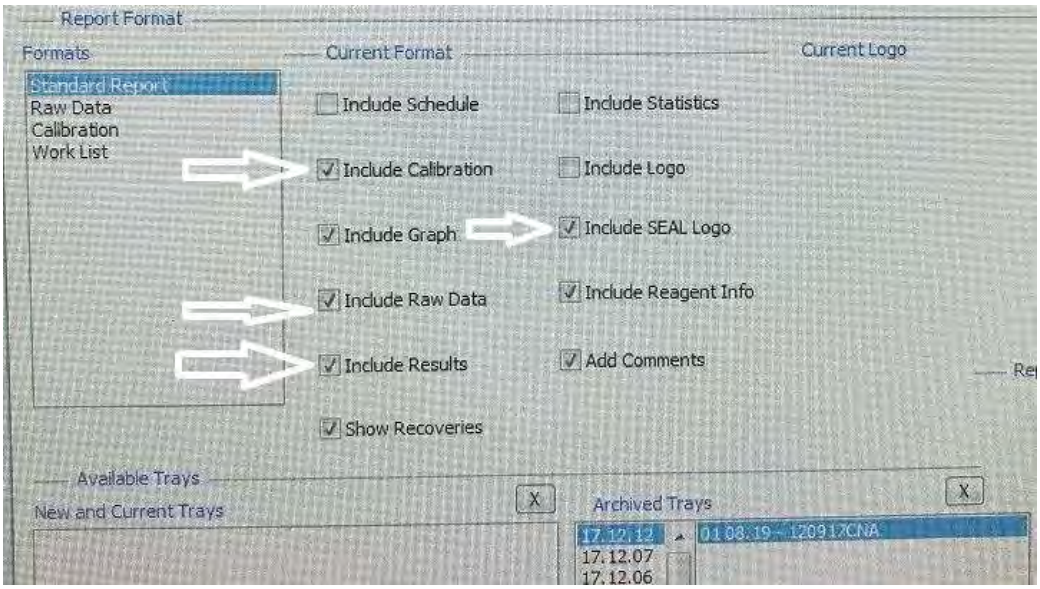
10.3.14 A pop-up box will appear with three options. Select Options 1 and 3 for Midi distilled sample analysis (Select only option 1 for SimpleDist® distilled samples) and click OK.

10.3.14.1 For SimpleDist® distilled sample analysis, the calibration standards, ICV/CCV and ICB/CCB are set up in the schedule using the distilled standards in individual sample cups, rather than a single position per section 10.3.3.



Calibration Standards are entered into the schedule as SS, S2, S3, S4, S5, S6, and S7, followed by ICV and ICB. The CCV and CCB must be put into the schedule in their required place every 10 samples.

10.3.15 Check the Calibration curve as soon as possible after the curve has completed running. Click the Calibration icon on the left hand side of the screen. Select CYANIDE and the date of the calibration. Review the curve according to the acceptance criteria.



10.3.16 When the analysis of the tray is complete, select Data Review from the left hand side of the screen. Choose the tray ID from the pop-up box and select OK. Review the run results. Click the Accept All icon. Choose Yes to keep the run, rename the file, and click save.

10.3.17 Click on the Reporting icon from the left menu on the Run screen.

10.3.18 From the pop-up box, choose to include Calibration, Raw Data, Results, and Logo. Highlight the file under the New and Current Tray column and click on Chronological Order Report. When the report appears, click Print.

10.3.19 When the run is finished and the report printed, open the Maintenance window. Choose Wash the Cuvette and click on Extra Wash. Repeat once.

10.3.20 Loosen the screw knobs (front-left and back-center) for the gold platens. Remove reagents, empty the waste container and dispose of the sample left in the autosampler cups.

10.3.21 Logout of the software, and turn the instrument off – large switch and then small switch.

11. CALCULATIONS / DATA REDUCTION

11.1 Total Cyanide concentrations are calculated by the instrument software by comparing sample peak heights with the calibration curve. The calibration curve is constructed by the software by plotting the standard concentrations vs peak heights, using linear regression. Conversion of results to µg/L is accomplished, where necessary, by multiplying results in mg/L by 1000.

For water samples: $C = A \times DF \times FV/IV$

Where:

C	=	Sample concentration in mg/L
A	=	Concentration from calibration curve in mg/L
DF	=	Dilution factor
FV	=	Final volume of distillate in mL
IV	=	Initial volume used for distillation in mL

For soil samples: $C = \frac{A \times DF \times FV}{IW \times S}$

Where:

C	=	Sample concentration in mg/kg, dry weight
A	=	Concentration from calibration curve in mg/L
DF	=	Dilution factor
FV	=	Final volume of distillate in mL
IW	=	Initial weight of sample distilled in g
S	=	Percent solids/100

Note: A Percent Solids determination must be performed on a separate aliquot when dry weight concentrations are to be reported. If the results are to be reported on a wet weight basis, the "S" factor should be omitted from the above equation. The "S" factor is not used in the calculation of results for tissue samples.

For wipe samples: $C = A \times DF \times FV \times 1000$

Where

C	=	Sample concentration in ug/wipe
A	=	Concentration from calibration curve in mg/L
DF	=	Dilution factor
FV	=	Final volume of distillate in L

11.2 Percent Recovery (%R) Calculation:

$$\%R = \frac{\text{observed value}}{\text{true value}} \times 100\,\%$$

11.3 The matrix spike and analytical spike percent recovery calculation:
MS Percent Recovery:

$$\text{MS \% Recovery} = \left(\frac{\text{Observed Conc. of MS} - \text{Conc. of Smp}}{\text{True Spike Conc.}} \right) \times 100\,\%$$

11.3.1 When sample concentration is less than the instrument detection limit, use 0 for sample results only for purposes of calculating percent recovery.

11.3.2 The units for reporting spike sample results will be identical to those used for reporting sample results (µg/L for aqueous and mg/Kg dry weight basis for solid).

11.4 Duplicate Sample Relative Percent Difference calculation:

$$RPD = \frac{|X_1 - X_2|}{\left(\frac{X_1 + X_2}{2}\right)} \times 100\,\%$$

Where:

X1 = Original Result
X2 = Duplicate Result

12. METHOD PERFORMANCE

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2 Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3 Method Detection Limit Study – A Method Detection Limit (MDL) study, as described in Detection Limits SOP PT-QA-007, must be performed initially and any time a significant

change is made to the analytical system. The MDL must be evaluated at least every 12 months.

12.3.1 Two LOQ verification standards shall be analyzed on each instrument every quarter. These standards may be used as the quarterly MDL points if analyzed at or below the RL.

12.4 Method 335.4 also requires a Linear Range Confirmation to be run every 6 months.

13. POLLUTION CONTROL

13.1 It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and PT-HS-001, Pittsburgh's Facility Addendum EH&S Manual.

13.2 This method does not contain any specific modifications that serve to minimize or prevent pollution.

14. WASTE MANAGMENT

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.1.1 Filter paper contaminated with bismuth, lead or cadmium sulfide: This waste is collected in waste containers identified as "Soils with Metals", waste stream #29.

14.1.2 Aqueous rinsates from distillation tube clean up: This waste is placed in containers identified as "Acid Waste", Waste #33. It is neutralized to a pH between 6 and 9 and disposed down a lab sink.

14.1.3 Unused sample distillates: This waste is placed in waste containers identified as "Sodium Hydroxide / Pyridine Waste", Waste #1.

14.1.4 Miscellaneous solid waste contaminated with sample residue, acids, caustics and reagents used in this SOP: This waste is placed in a trash container and disposed with regular trash.

14.1.5 Aqueous analytical waste, neutral to slightly basic, contaminated with 3% pyridine: This waste is placed in waste containers identified as “Sodium Hydroxide / Pyridine Waste”, Waste #1.

14.1.6 Aqueous alkaline material from the auto-analyzer/titrations: This waste is placed in waste containers identified as “Sodium Hydroxide / Pyridine Waste”, Waste #1.

16. METHOD MODIFICATIONS

16.1 According to Method 335.4, section 10.5, calibration standards are to be analyzed in order of decreasing concentration. TestAmerica Pittsburgh will analyze the calibration curve in order of increasing standard concentration for all methods referenced.

16.2 The initial calibration curve concentrations given in SW846 method 9012B section 7.4.1 and 9014 section 7.3.1 are replaced with a shorter range curve in section 7.5.5 of this SOP.

16.3 Sample pre-treatment sulfide by method SM4500-CN^- C using Lead Carbonate is performed using Cadmium Carbonate by this SOP (from method 335.4).

16.4 The sample duplicate required by section 8.4 of method 9010C may be replaced by the performance of an MS and MSD, since CN is not often detected in samples and the MS/MSD provides a better chance of measuring the method precision.

16.5 A matrix spike concentration of 200 ug/L is used for all methods, instead of the 40 ug/L mentioned in section 8.5 of method 9010C/9012B.

16.6 The SimpleDist® distillation procedure uses proportional reduced volumes of the reagents required by method 335.4 and 9010C. The SimpleDist® distillation time has been reduced to 45 minutes per the reduced volume and manufacturer's instructions.

18.12 Changes to current revision

SOP section	Change from	Change to	Reason
1.2	RL of 0.005 mg/L	RL of 0.010 mg/L	Correction
4.2		Added or ascorbic acid	Option
4.3	Removed bismuth nitrate		Lab not using
5.6 Table	Removed bismuth nitrate	Added ascorbic acid, chloramine-T and barbituric acid	Correction
6.2		Added requirement to verify SimpleDist tube volume	Clarification
7.2.7	Removed bismuth nitrate		Correction
7.2.9		Added ascorbic acid	Option
7.5.5.1		Added Calibration Preparation Standard 0.5 mg/L	Clarification
7.5.5.2	Removed 0.005 mg/L standard	Added 0.25 mg/L standard and updated standard preparation volumes for 6mL used for SimpleDist procedure	Correction
7.5.5.3		Added “for Midi distillation”	Clarification
7.5.6 & 7.5.7		Added “Not distilled for Midi”	Clarification
9.2.2	0.5g soil for SimpleDist	0.2g	Correction
9.9.1 bullet 1	0.06mL for 0.10mg.L spike	0.12mL for 0.20mg/L spike	Correction
10.1.2	removed		Bismuth nitrate not used
10.2.1.1	Dropwise 5N NaOH	1ml of 1N NaOH	Correction
10.2.1.2		Added or 0.06g ascorbic acid	Option
10.2.1.2 & 10.2.1.3		Added if any samples treated, MB & LCS must have treatment added	Correction

10.2.4	0.5g soil for SimpleDist	0.2g	Correction
10.2.20, 16.6	90 minutes	45 minutes for SimpleDist	Correction
10.2.24		Add to let samples cool 30 minutes	Correction
10.3.3		Corrected section 7 references	Correction
10.3.3.1 & 10.3.3.6		Added positions used only for Midi distilled sample analysis	Clarification
10.3.14		Added only option 1 checked for SimpleDist distilled sample analysis	Clarification
10.3.14.1		Added for SimpleDist sample analysis standards placed in schedule	Clarification
12.3 & 15.6	CA-Q-S-006	PT-QA-007	Correction
16.2	Reference to SOP 7.4.5.1	7.5.5	Correction
16.5	Spike 0.1 mg/L	Spike 0.2 mg/L	Correction

This documentation has been prepared by TestAmerica Laboratories, Inc. d/b/a Eurofins TestAmerica and its affiliates ("Eurofins TestAmerica"), solely for their own use and the use of their customers in evaluating their qualifications and capabilities in connection with a particular project. The user of this document agrees by its acceptance to return it to Eurofins TestAmerica upon request and not to reproduce, copy, lend, or otherwise disclose its contents, directly or indirectly, and not to use it for any purpose other than that for which it was specifically provided. The user also agrees not to give access to this document to any third parties including but not limited to consultants, unless such third parties specifically agree to these conditions.

THIS DOCUMENT CONTAINS VALUABLE CONFIDENTIAL AND PROPRIETARY INFORMATION. DISCLOSURE, USE OR REPRODUCTION OF THESE MATERIALS WITHOUT THE WRITTEN AUTHORIZATION OF EUROFINS TESTAMERICA IS STRICTLY PROHIBITED. THIS UNPUBLISHED WORK BY EUROFINS TESTAMERICA IS PROTECTED BY STATE AND FEDERAL LAW OF THE UNITED STATES. IF PUBLICATION OF THIS WORK SHOULD OCCUR THE FOLLOWING NOTICE SHALL APPLY:

©COPYRIGHT 2019 TESTAMERICA LABORATORIES, INC. d/b/a EUROFINS TESTAMERICA ALL RIGHTS RESERVED.

1. SCOPE AND APPLICATION

1.1. This method is applicable to the determination of ignitability of solids as it pertains to waste characterization outlined in Chapter 7 of EPA SW846. It is used to identify wastes that either present fire hazards under routine storage, disposal and transportation or are capable of "severely exacerbating" a fire that is already burning.

1.2. There is no instrument or method detection limit applicable to this test. Results are reported qualitatively as either "Yes" or "No" depending on the ignitability of the sample.

1.3. Applicable Matrices: Solids, including domestic and industrial wastes, sludges, and petroleum wastes.

1.4. The analytical time depends on the matrix and method of analysis. For solids, the analytical time is approximately 5 minutes.

1.5. On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department or the Laboratory or Technical Director and documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1. Solids are analyzed by exposure to open flame for a set length of time after which the flame is removed and the sample observed to determine its ignitability characteristic. If the material will burn, a subsequent set of tests determine ignitability according to the definitions in Chapter 7 of SW-846.

3. DEFINITIONS

3.1. Ignitability - The capability of a solid sample, under standard conditions of temperature and pressure, to cause fire through friction, moisture absorption, or spontaneous chemical changes and, when ignited, to burn so vigorously and persistently as to create a hazard.

3.2. TALS – TestAmerica Laboratory Information Management System

3.3. NCM - Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.4. Refer to the glossary in the Laboratory Quality Assurance Manual (PT-QA-M-001) for general laboratory definitions.

4. INTERFERENCES

4.1. Improper storage of samples may cause loss of volatiles and lead to erroneous results.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2. Because of the unknown reactivity of the materials being tested, the sash of the hood should be lowered to shield the operator. As an alternative, the operator may use a face shield if using a sash is not possible.

5.3. In the event a sample ignites in the test apparatus do not attempt to remove the sample. Turn off the apparatus and flame. The flame should go out when the cup is closed. If this does not happen the flame may be extinguished by covering the sample with a non-flammable material. After the apparatus has cooled the sample may be removed.

5.4. Eye protection that protects against splash and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

NOTE: In addition to safety glasses a face shield should also been worn when performing this procedure. The hood sash should also be pulled down to act as an additional barrier when performing this procedure.

5.5. There are no materials used in this method that have a serious or significant hazard rating.

5.6. Exposure to chemicals must be maintained **as low as reasonably achievable**, therefore, unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.7. In order to stabilize conditions during the actual test, the fume hood when the test is being conducted may be turned off.

5.8. All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica's associate. The situation must be reported **immediately** to a laboratory supervisor and/or the EH&S Coordinator.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1. Ceramic crucibles, 50 mL capacity

6.2. Source of open flame: "barbecue" butane lighter, or equivalent. **NOTE:** a butane cigarette lighter, short wooden matches, or a high temperature propane torch are **NOT** an acceptable alternative. The flame source must allow the analyst to remain away from the sample.

7. REAGENTS AND STANDARDS

7.1. There are no reagents and standards required for this method.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1. Sample container, preservation techniques and holding times may vary and are dependent on sample matrix, method of choice, regulatory compliance, and/or specific contract or client requests. Listed below are the holding times and the references that include preservation requirements.

Matrix	Sample Container	Minimum Sample Size	Preservation	Holding Time
Solid waste, sludges, petroleum waste	Glass	10 g	>0.0˚C but ≤ 6.0 ℃	None

NOTE: No chemical preservation is required or appropriate

9. QUALITY CONTROL

9.1. Sample/Sample Duplicate (DUP) - One Sample/Sample Duplicate pair must be processed for each QC batch of 20 samples. The QC batch is defined as a set of up to 20 field samples plus associated laboratory QC samples that are similar in composition (matrix) and that are processed within the same time period using the same reagent and standard lots.

NOTE: All samples that are YES for ignitability are analyzed in duplicate for confirmation purposes.

9.1.1. The results of the DUP pair are used to determine analytical variability.

9.1.2. The DUP pair is evaluated qualitatively. If both the sample and its duplicate are found to be either both ignitable (YES/YES) or both not ignitable (NO/NO), the QC is considered in control.

9.1.3. The DUP QC is out of control if the two results are different (YES/NO). In this case, the data must be qualified appropriately (e.g. sample heterogeneity) and an explanation provided in the report narrative.

9.2. There are no other QC analyses applicable to this test.

10. PROCEDURE

10.1. This method has no calibration or standardization requirements.

10.2. Any significant variation in procedure shall be completely documented using an NCM.

10.3. In a fume hood, place a small quantity of sample (approximately 1 gram) into the ceramic crucible. It is not necessary to weigh the sample, but a small quantity should be used to minimize any potential hazards.

10.4. Wear a face shield in addition to safety glasses, or pull the hood sash down to act as a shield. Turn off the hood (if necessary to maintain a stable flame), touch the ignition source (see section 6.2) to the sample. Keep the flame in contact with the sample for 5 ± 2 seconds.

10.5. Remove the ignition source and observe the sample.

10.6. Observations can be reduced to three broad categories:

Reaction of Sample	Classification
Sample does **not** ignite	Not ignitable, no further testing necessary
Sample ignites but burns only in contact with flame	Not ignitable, no further testing necessary
Sample ignites and burns continuously	Proceed to section 10.6.1

10.6.1. Wear a face shield in addition to safety glasses, or pull the hood sash down to act as a shield for the following steps. Place approximately 5g of solid into a crucible and stir for 10 seconds. If the sample ignites and burns continuously, then it is classified as ignitable. If not, proceed to section 10.6.2

10.6.2. Add 5 mL of water to the sample in the crucible. If the sample ignites and burns continuously, then it is classified as ignitable. If not, proceed to section 10.6.3.

10.6.3. Add approximately 5g of solid to a crucible. Heat the crucible from underneath with a burner for 30 seconds. If the sample ignites and burns continuously, then it is classified as ignitable. If not, the sample is classified as not ignitable.

11. DATA ANALYSIS AND CALCULATIONS

11.1. If the result is “Ignitable”, report as “Yes”.

11.2. Samples which do not meet the “Ignitability” criteria should be reported as “No.”

11.3. The sample information is directly entered into the TALS Batch Results.

12. METHOD PERFORMANCE

12.1. The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC.

12.2. Demonstration of Capability – Prior to the analysis of samples, a Demonstration of Capability (DOC) as described in the QA Manual must be performed.

12.3. Method Detection Limit Study does not apply to this procedure.

13. POLLUTION CONTROL

13.1. All waste will be disposed of in accordance with Federal, State and Local regulations. Where reasonably feasible, technological changes have been implemented to minimize the potential for pollution of the environment. Employees will abide by this method and the policies in section 13 of the Corporate Safety Manual for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2. This method does not contain any specific modifications that serve to minimize or prevent pollution.

14. WASTE MANAGEMENT

14.1. The following waste streams are produced when this method is carried out.

14.2. Excess non-flammable samples. This waste is placed in waste containers identified as "Mixed Flammable Solvent Waste", Waste #3.

14.3. Excess flammable samples and waste solvents. This waste is placed in waste containers identified as "Mixed Flammable Solvent Waste", Waste #3.

THIS DOCUMENT CONTAINS VALUABLE CONFIDENTIAL AND PROPRIETARY INFORMATION. DISCLOSURE, USE OR REPRODUCTION OF THESE MATERIALS WITHOUT THE WRITTEN AUTHORIZATION OF EUROFINS TESTAMERICA IS STRICTLY PROHIBITED. THIS UNPUBLISHED WORK BY EUROFINS TESTAMERICA IS PROTECTED BY STATE AND FEDERAL LAW OF THE UNITED STATES. IF PUBLICATION OF THIS WORK SHOULD OCCUR THE FOLLOWING NOTICE SHALL APPLY:

©COPYRIGHT 2020 TESTAMERICA LABORATORIES, INC. d/b/a EUROFINS TESTAMERICA ALL RIGHTS RESERVED.

1. SCOPE AND APPLICATION

1.1. This method is applicable to the determination of pH in waters, wastewaters, solids and wastes. It is based on SW846 Methods 9040 B & C and 9045 C & D and Standard Method 4500-H^+B. The working range is 1 - 14 pH units.

1.2. For pH in waste, sediment, or sludge, if water is present at < 20% of the total sample volume, by visual estimate, the sample is treated as a solid, and method 9045C or D is used. If water is present at > 20% of the total volume, the sample may be analyzed using method 9040B or C.

1.3. On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department or the Laboratory or Technical Director and documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1. The pH is determined electrometrically. The pH meter is calibrated with a series of known pH buffers. The impact of the actual sample temperature is electronically compensated for using Automatic Temperature Compensation (ATC).

NOTE: The use of ATC does not adjust the pH reading at the current sample temperature to what it would be at 25°C. If the pH at a specified temperature, such as 25°C, is required, the sample must be warmed/cooled in a water bath before analysis.

2.2 The analysis may be performed by the Autotitrator for clean water samples.

3. DEFINITIONS

3.1. TALS – TestAmerica Laboratory Information Management System

3.2. NCM – Non-Conformance Memo - a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3. Refer to the glossary in the Laboratory Quality Assurance Manual (PT-QA-M-001) for additional definitions.

4. INTERFERENCES

4.1. Samples with very low or very high pH may give incorrect readings on the meter. For samples with a true pH of >10, the measured pH may be incorrectly low. This error can be minimized by using a low-sodium-error electrode.

4.2. Extreme temperatures can affect the pH reading even with the automatic temperature compensation. Samples should be analyzed near room temperature.

4.3. Coatings of oily material or particulate matter can impair electrode response. These may be removed by gentle wiping or detergent washing the electrode followed by a deionized water rinse. Treatment with 1:10 HCl may be necessary to remove the film, followed by a deionized water rinse.

4.3.1. Samples may not be filtered to remove particles prior to analysis.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

The following is a list of the materials used in this method, which have a serious or significant hazard rating. This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material (1)	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Hydrochloric Acid	Corrosive Poison	5 ppm-Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failure, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
1 – Always add acid to water to prevent violent reactions.			
2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.2. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.3. All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1. pH meter with combination pH electrode and automatic temperature compensation

- Accumet XL15, Accumet AR25, or equivalent

6.2. Snap Top Bottles, 2 oz and 4 oz

6.3. Top loading balance: Capable of accurately weighing ± 0.01 g

6.4. Stir plate and stir bars

6.5. Mechanical Shaker

6.6. Automated analysis option: Man-Tech MT-100 Autotitrator with PC-Titrate™ software and Automax73 autosampler with 50 mL sample tubes

7. REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard.

7.1. Standards

7.1.1. pH 2, 4, 7, 10 and pH 13 buffers, purchased with certificate of analysis, use manufacturer's expiration date. Store buffers at room temperature.

7.1.2. Second source pH 7 buffer, purchased with certificate of analysis, use manufacturer's expiration date. Store buffer at room temperature.

7.1.3. Fresh buffers are poured from the main container into closed lid cups for daily use.

7.1.4. Concentrated Hydrochloric acid (HCl)

7.1.4.1. 1:10 HCl Cleaning Solution – slowly add 20 mL concentrated HCl to 100 mL of laboratory reagent water in a 200 mL volumetric flask. Mix well and dilute to volume.

7.1.5. Acetone may be used to remove oily substances from the probe, followed by a thorough water rinse.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1. Samples may be collected in glass or plastic containers.

8.2. This analysis should be performed in the field within 15 minutes of sampling for all matrices. If samples are analyzed in the laboratory, beyond the 15 minutes, results shall be reported with an "HF" qualifier to indicate that the technical holding time was exceeded.

8.3. Samples are to be shipped and stored at >0.0°C but ≤6.0°C. No chemical preservation is required or permitted.

9. QUALITY CONTROL

9.1. A batch is a group of 20 or fewer samples of similar matrix excluding QC samples (LCS, and sample DUP) that are processed together in the same 24 hour period.

9.2. Duplicates - Sample duplicates are performed at a minimum frequency of one per every 10 samples (or fewer) of the same matrix. The %RPD between sample and duplicate must be ≤ 2%.

9.2.1. If the %RPD exceeds 2%, two fresh portions of sample and duplicate must be analyzed until the readings stabilize within the required limit.

9.3. ICV/LCS: second source pH buffer 7 is analyzed after the initial calibration. The pH readings must be 6.95 to 7.05 pH units.

9.3.1. If the ICV reading is outside the range, repeat once with a fresh portion of second source buffer. If the failure repeats, the initial meter calibration must be repeated with fresh buffers. Sample analysis must not proceed until the meter calibration is verified successfully.

9.4. CCV: pH buffer 7, same source as the calibration, is analyzed after every 10 samples and at the end of the sequence. The pH readings must be 6.95 to 7.05 pH units.

9.4.1. If a CCV falls outside the required range, repeat once with a fresh portion of buffer. If the failure repeats, the initial meter calibration must be repeated with fresh buffers. All samples analyzed after the last passing CCV must be reanalyzed.

9.5. Any unauthorized deviations from this procedure must also be documented as a nonconformance, using the appropriate NCM.

10. PROCEDURE

10.1. Calibration

10.1.1. Initial Calibration

10.1.1.1. Refer to the manufacturer's manual for instrument specific calibration steps.

10.1.1.2. The following procedure is applied when calibrating the manual pH meter:

- Prior to taking any pH readings, check that the fill hole at the top of the pH probe is open.
- Rinse the electrodes with reagent water and place in the pH 4.0 buffer. Enter the value (4.0) of the standard into the pH meter using the touch screen. Allow the value to stabilize.
- Rinse the electrodes and place in the pH 7.0 buffer. Enter the value (7.0) of the standard into the pH meter using the touch screen. Allow the value to stabilize.
- Repeat these steps for the 2, 10 and 13 pH buffers.

10.1.1.3. The pH meter must be calibrated daily or each day it is used. The calibration is recorded on the analytical log sheet. The slope of the calibration must meet $\geq$ 95%, or the manufacturer's requirements if tighter. If the manufacturer's slope requirement is not met, the meter

will display an error message. Pour fresh buffer solutions into the cups and repeat the calibration. If this does not resolve the problem, change the KCL solution in the electrode. If still having a problem the probe may need to be changed. Note any needed maintenance in the meter maintenance log, including electrode maintenance.

10.1.1.4. The pH readings must be within 0.05 pH units of each buffer solution value. If not repeat adjustments on successive portions of the two buffer solutions until the readings are within 0.05 pH units (s.u.).

10.1.1.5. The following procedure is applied when calibrating the Autotitrator:

- Empty the waste container and fill the DI Rinse jugs with fresh reagent water daily before beginning calibration / analysis.
- Fill autosampler tubes with fresh 2, 4, 7, 10 and 13 pH buffers. Use one tube per buffer, the instrument will pull multiple aliquots.
- Click load template and select **pH X 3 CAL**
- Click **START**. The meter will proceed with the calibration and will indicate if any of the slope and individual pH readings do not meet criteria.

10.1.1.6. If the pH meter has been turned off, it must be calibrated prior to use.

10.1.1.7. After the calibration the ICV/LCS, a second source pH 7 buffer, is analyzed before sample analysis. The pH readings must be 6.95 – 7.05 pH units. This standard also serves as the LCS.

10.1.2. Calibration Check / Continuing Calibration

10.1.2.1. The CCV, which is a 7 buffer of the same source as the calibration standard, is analyzed after every ten samples to ensure the calibration remains linear.

10.1.2.2. The pH meter must be recalibrated if the buffer is not within 6.95-7.05 pH units. If this range is exceeded, reanalyze all samples analyzed since the last pH buffer that met criteria.

10.1.2.3. If samples of extreme pH are included in the batch (<4 or >10), it may be appropriate to analyze a CCV buffer close to the pH of the samples, in addition to the CCV 7 buffer.

10.2. Sample Preparation:

10.2.1. Waters (Method 4500H+ B or 9040B/C)

10.2.1.1. No preparation necessary for waters and wastewaters.

10.2.1.2. Waters should be allowed to equilibrate to near room temperature prior to analysis. Temperature is recorded on worksheet. The pH meter is equipped with a temperature probe, and calibration is verified quarterly.

10.2.2. Solids (Method 9045C/D)

10.2.2.1. Place 20 g (± 0.5 g) of sample into a beaker or other suitable container. (A sample size of less than 20 g can be used as long as the 1:1 weight to volume relationship is maintained.)

10.2.2.2. Add 20 mL of reagent water and mix for five minutes.

NOTE: In the event a sample absorbs the water, additional water will be added at 5 mL increments until sufficient liquid is obtained to cover the pH probe. An NCM will be written to document this anomaly.

10.2.2.3. Allow sample to stand for one hour to allow the solids to settle out or centrifuge off the aqueous phase for pH measurement.

10.2.2.4. Sediments, sludges and wastes: based upon the nature of the sample matrix, the analyst will use appropriate technical judgment, per section 1.2, and prepare the sample according to either 10.2.1 or 10.2.2

10.3. Sample Analysis

Prior to taking any pH readings, check that the fill hole at the top of the pH probe is open.

10.3.1. Manual Waters

10.3.1.1. Place 2 aliquots of the sample in 2 clean Snap Top bottles using a sufficient volume to cover the sensing elements of the electrode (approximately 20 mL). Allow the pH to stabilize (swirling or stirring may quicken stabilization). Record the pH on the analytical log sheet. Remove the electrodes from the sample. Rinse and gently dab off the electrodes between each measurement. Repeat measurement on successive volumes of sample until values differ by less than 0.1 pH units. Report the last reading that is within acceptance range. Store the electrodes in pH 4 buffer or manufacturer's storage solution when not in use.

10.3.2. Autotitrator Waters

10.3.2.1. Load Template **pH X 3**

10.3.2.2. Click **Add rows** and type in the number of spaces for samples and QC in the batch.

10.3.2.3. Scan in samples and type in QC IDs

10.3.2.4. Click and drag the number of vials down in the vial column.

10.3.2.5. Click and drag the schedule and order number columns down. (Hold CTRL, click on the cell and drag it down to the last cell.)

10.3.2.6. Save the Template as MMDDYYPH, for example 100120PH.

10.3.2.7. Fill autosampler tubes according to the schedule. Use one tube per sample and QC, the instrument will pull multiple aliquots.

10.3.2.8. Click **START**.

10.3.2.9. Example Sequence:

Tap
DI Rinse
LCS
Sample
Sample Duplicate
8 more samples
CCV

-CCV after every 10 samples
-Close with CCV and 2 DI Rinses

10.3.3. Solids (Supernatant)

10.3.3.1. Immerse the pH electrodes in the supernatant layer of the sample - be careful not to stir up solids. Allow pH to stabilize and record it on the analytical log sheet. Remove and rinse the electrodes between each measurement. Store electrodes in pH 4 buffer or manufacturer's storage solution when not in use.

10.3.3.2. If the sample contains oil or other substances that will coat or damage the electrodes, the pH should be analyzed using pH Paper Method if client allows this change.

10.3.4. If the pH of the sample is >12.0, the pH must be measured at 25 ± 1 ºC. Use a water bath set at this temperature to warm a portion of the sample in a closed container.

10.4. Autotitrator Data Upload

10.4.1. To begin the data export to TALS, select "Export" under the "File" option at the top left of the screen of the Water Analysis Historical Data Report. A box will pop up with options for file type and file name:

- Change the File Type by selecting "Fixed Field ASCII File"(.TXT)" from the drop down menu.
- Change the File Name by clicking the ",,," box next to the File Name box. Name the file for the date of the run and analysis type (for example: 102120PH).
- Click "OK" to save the file.

10.4.2. Open the software "ManTech FT" from the PC desktop.

10.4.3. Open the saved data file in .TXT form by clicking the "…" box located to the right of the "Raw Data File" option. Select the appropriate data file and click "OK.

10.4.4. DO NOT CHANGE THE IMPORT PATH.

10.4.5. On the bottom of the ManTech FT software [age, click "Load Preset".

10.4.6. In the box that pops up, select pH.

10.4.7. Be sure to select pH, pH2, pH3, and Temperature, temp2 and temp3 from the Available Analytes list to report all readings.

10.4.8. After verifying that the data series selected are correct, click "Transfer File". A box will pop up to let the user know that the file transfer has been completed.

10.5. Analytical Documentation

10.5.1. All analytical information, results and associated QC, are electronically recorded in TALS as the analysis is performed, including the analytical data from standards and any corrective actions or modifications to the method. The time of the individual sample readings is documented in the TALS batch. (Autotitrator will upload analysis times.)

10.5.2. All standards are logged into the TALS reagent module. All standards are assigned a unique number for identification, and this number is recorded in each analytical batch. Standards entry is reviewed by the supervisor or designee.

10.5.3. Daily meter calibration is documented in the Meter Calibration log, specific to each pH meter. The Autotitrator calibration will be included with the raw data.

11. CALCULATIONS / DATA REDUCTION

11.1. Any sample with a pH < 2 or > 13 will need to have a "cn" qualifier added plus an NCM stating "The pH is estimated because the result is outside the calibrated range of pH 2-13."

12. METHOD PERFORMANCE

12.1. The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples.

12.2. Demonstration of Capability - Prior to analysis of any client samples, the analyst must demonstrate their ability to successfully analyze samples. This demonstration shall consist of calibrating the pH meter (slope meeting manufacturer's control limit) and analyzing 4 LCS (pH 7) standards. The results of the 4 LCSs must all be within 6.95-7.05. DOCs are repeated annually and any time a significant change Is made to the analytical procedure.

12.3. Determination and verifications of MDL and RL are not applicable to this procedure.

13. POLLUTION CONTROL

13.1. All waste will be disposed of in accordance with Federal, State and Local regulations. Where feasible, technological changes have been implemented to minimize the potential for pollution of the environment. Employees will abide by this method and the policies in section 13 for "Waste Management and Pollution Prevention" of the Corporate Environmental Health & Safety Manual (CW-E-M-001) and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2. This method does not contain any specific modifications that serve to minimize or prevent pollution.

14. WASTE MANAGEMENT

14.1. Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.2. The following waste streams are produced when this method is carried out.

14.2.1. Acidic sample waste generated by the analysis. This waste is checked with pH paper, neutralized to a pH between 6 and 9 and discharged down a lab sink.

14.2.2. Alkaline sample waste generated by the analysis. This waste is checked with pH paper, neutralized to a pH between 6 and 9 and discharged down a lab sink.

14.2.3. Exhausted oil samples utilized in the analysis. This waste is collected in waste containers identified as "Mixed Flammable Solvent Waste", Waste #3.

14.2.4. Solvent waste generated by the analysis. This waste is collected in waste containers identified as "Mixed Flammable Solvent Waste", Waste #3.

14.2.5. Exhausted acidic and/or alkaline buffer solutions utilized in the analysis. This waste is checked with pH paper, neutralized to a pH between 6 and 9 and discharged down a lab sink.

14.2.6. Exhausted soil samples utilized in the analysis. This is collected in containers identified as "Lab Trash", Waste #12.

1.0 Scope and Application

1.1 This method quantifies the n-hexane extractable material (HEM; Oil and Grease) and n-hexane extractable material that is not adsorbed by silica gel (SGT-HEM or TPH (non-polar material)) in surface and saline waters and aqueous wastes. Generally, the extractables consist of non-volatile hydrocarbons, vegetable oils, animal fats, waxes, soaps, greases, and similar materials.

1.2 This method is for use in the Environmental Protection Agency's (EPA's) survey and monitoring programs under the Clean Water Act; the Resource Conservation and Recovery Act; the Comprehensive Environmental Response, Compensation, and Liability Act; and other EPA regulatory programs. "Oil and grease" is a conventional pollutant under the Clean Water Act and codified at 40 CFR 401.16. The term "n-hexane extractable material" reflects that this method can be used to determine materials other than oils and greases. Similarly, the term "silica gel treated n-hexane extractable material" reflects that this method can be used to determine material that is not adsorbed by silica gel (non-polar material).

1.3 If only SGT-HEM is required, the HEM determination can be skipped only if the HEM concentration is known. If the HEM concentration is not known, then the HEM determination must be performed prior to the SGT-HEM determination.

1.4 This method is applicable to surface waters, sewages, and aqueous wastes containing approximately 5 mg/L to approximately 1000 mg/L using a 1L sample. The reporting limit for both HEM and SGT-HEM is 5 mg/L. These limits may be extended to higher levels by analysis of a smaller sample volume collected separately. Dilutions are not appropriate for this procedure, except as specifically described for silica gel treatment in section 10.23.2.

1.5 On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department or the Laboratory or Technical Director and documented fully in an NCM that accompanies the analytical batch.

2.0 Summary of Method

2.1 Using a solid phase extraction manifold, a 1.0 L aqueous sample (acidified to pH <2) is filtered through an extraction disk. The extractable materials are rinsed from this disk with n-hexane, collected into a 40 ml VOA vial. The extract is filtered through phase separation filter paper into a pre-weighed pan, for evaporation on the Speedvap 9000 II. This step concentrates the HEM portion of the sample. The pans are allowed to cool in a desiccator, and then re-weighed to determine the HEM concentration.

2.2 In order to determine the SGT-HEM (TPH), the residue from the sample is then reconstituted with hexane and treated with silica gel. The silica gel treated extract is filtered into a pre-weighed pan, for evaporation on the Speedvap 9001. This step concentrates the SGT-HEM portion of the sample. The pans are allowed to cool in a desiccator, and then re-weighed to determine the SGT-HEM concentration.

3.0 Definitions

3.1 N-hexane extractable material (HEM): Material that is extracted from a sample with hexane and determined by this method (oil and grease). Examples of this material include relatively non-volatile hydrocarbons, vegetable oils, animal fats, waxes, soaps, greases, and other materials with similar characteristics.

3.2 Silica gel treated n-hexane extractable material (SGT-HEM): Material that is extracted from a sample with hexane and determined by this method that is not adsorbed by silica gel (TPH).

3.3 TALS: TestAmerica Laboratory Information Management System

3.4 NCM: Non-Conformance Memo, a communication system for the laboratory to document anomalies or non-conformances encountered with samples and their analysis.

3.5 See TestAmerica Pittsburgh Laboratory's Quality Assurance Manual (PT-QA-M-001) for glossary of common terms.

4.0 Interferences

4.1 This method is not designed to quantify substances which volatilize at temperatures below approximately 85°C. Petroleum products, ranging from gasoline to #2 fuel oils, may be partially lost during the extraction and concentration process. Certain crude or heavy oils contain portions of material not soluble in n-hexane, often resulting in low recoveries.

4.2 All glassware and other apparatus in contact with the sample must be thoroughly washed and solvent rinsed to eliminate contamination from artifacts. In addition, reagent grade or better solvents must be used to ensure that the glassware, etc. is free of artifacts. The hexane, silica gel, phase separation paper, and any drying agents used, must be shown to be free from residue down to the MDL level.

4.3 For samples consisting of complex matrices (such as particulates or detergents) that may interfere with the extraction process, a smaller sample size may be used.

4.4 Care must be taken to avoid contamination of the final extract with sodium sulfate, silica gel and/or water. This can be avoided by filtering the HEM or SGT-HEM very slowly. Should contamination occur, apparent by visible amounts of crystalline material in the residue, the residue must be re-suspended in n-hexane.

The re-suspended material can be filtered with additional solvent washings of the flask through phase separator filter paper. The method then resumes with the evaporation process.

4.5 Samples must be brought to room temperature prior to analysis in order to reduce the amount of solid material adhering to the walls of the collection containers. Erroneous low results may be obtained from samples analyzed at refrigeration temperatures.

5.0 Safety

5.1 Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2 The following is a list of the materials used in this method, which have a serious or significant hazard rating. This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material (1)	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Acetone	Flammable	1000 ppm-TWA	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Hexane	Flammable Irritant	500 ppm-TWA	Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Vapors may cause irritation to the skin and eyes.
Hydrochloric Acid	Corrosive Poison	5 ppm-Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failure, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Methanol	Flammable Poison Irritant	200 ppm-TWA	A slight irritant to the mucous membranes. Toxic effects exerted upon nervous system, particularly the optic nerve. Symptoms of overexposure may include headache, drowsiness and dizziness. Methyl alcohol is a defatting agent and may cause skin to become dry and cracked. Skin absorption can occur; symptoms may parallel inhalation exposure. Irritant to the eyes.
1 – Always add acid to water to prevent violent reactions.			
2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.3 Eye protection that protects against splash, Laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. . Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.4 Exposure to chemicals must be maintained as low as reasonably achievable, therefore, unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.5 The preparation of standards and reagents will be conducted in a fume hood with the sash closed as far as the operations will permit, or under other adequate ventilation.

5.6 All work must be stopped in the event of a known or potential compromise to the health and safety of an Eurofins TestAmerica Pittsburgh Associate. The situation must be reported immediately to a supervisor or the EH&S coordinator.

6.0 Equipment and Supplies

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 Analytical balance capable of weighing to 0.1 mg

6.2 Vacuum source and tubing to connect apparatus

6.3 Waste receptacle and tubing to connect manifold

6.4 Horizon SpeedVap 9000II

6.5 UCT ENVIRO-CLEAN® Oil and Grease extraction apparatus equipped for each unit with the following:

- 6.5.1 1.0 L reservoir funnel
- 6.5.2 Rinsing flask (one per manifold set-up)
- 6.5.3 UCT ENVIRO-CLEAN® Oil and Grease cartridges – 37mm diameter polypropylene cartridge design
- 6.5.4 Oil-less vacuum pump for the UCT cartridge system (Rocker Model 400)

6.6 Desiccator

6.7 70 & 150 ml Disposable Evaporation Pans

6.8 Glass, class A, graduated cylinders, 1 L and 100 mL

6.9 pH indicator strips

6.10 40 mL VOA vials or other suitable glass container used as Collection flasks

6.11 Phase separation filter paper

6.12 Glass filter funnels

6.13 Glass Stir Rods, 4 x 125 mm or similar

7.0 Reagents and Standards

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard. Quantities different from what is specified can be prepared, provided that the ratios remain the same.

All chemicals must be ACS reagent grade or better. Solvents must be of a grade shown to produce residue <1.0mg/L when evaporated.

7.1 Reagent water- Super Q or DI water

7.2 Hydrochloric acid or sulfuric acid, 6N: Mix equal volumes of concentrated HCl and reagent water or 1 part H_2SO_4 and 5 parts reagent water to produce an approximately 6N solution.

7.3 Acetone

7.4 n-Hexane, 85% minimum purity, 99.0% minimum saturated C6 isomers

7.5 Methanol

7.6 Silica Gel: Anhydrous, 75-150µm, 30 Å pore size (Dry at 200-250^{o}C for a minimum 24 hours and store in a desiccator or tightly sealed containers)

7.6.1 Verify that the n-hexane soluble material content of the silica gel is <5mg per 30g. Extract 30g of silica gel with 40-50mL of n-hexane by shaking in a closed container, using a wrist action or shaker table, for 15 minutes. Filter the extract into a tared evaporating dish with phase separation filter paper and evaporate the solvent. The final residue must be <0.0050 g (<0.17mg residue / g silica gel).

7.7 Hexadecane/stearic acid Spiking Standard (Used for LCS and MS/MSD)

7.7.1 Purchased Speedisk Oil and Grease standards kit of 2 mg/mL stearic acid and 2 mg/mL hexadecane in acetone. Spike 10.0 mL of the solution into a 1 L aliquot of acidified reagent water (acidified with 5 mL of 1:1 HCl)for the LCS, or separate sample bottles for MS/MSD. The resulting concentrations in the LCS are 40 mg/L HEM and 20 mg/L SGT-HEM (stearic acid is removed by the silica gel treatment. Refer to the manufacturer's expiration date.

7.8 Laboratory Prepared Spiking Solution (optional)

7.8.1 The spiking solution may be prepared by weighing 200 ± 2 mg hexadecane and 200 ± 2 mg stearic acid into a 100 mL volumetric flask. Dilute to

volume with acetone. Store in the dark at room temperature. To minimize evaporation of acetone, wrap the stopper and neck area of the flask with parafilm. Sonicate and warm to provide adequate dissolution of the solution. Prior to use, verify that the solution level is at the 100mL mark. In the event that some acetone has evaporated, bring the solution to volume again with acetone. Standard expiration is 6 months from the date prepared.

Note: Stearic acid tends to stick to everything. It is very important that all surfaces of the sample bottle, and anything else the sample comes in contact with, are rinsed well with hexane to ensure complete recovery.

8.0 Sample Collection, Preservation, Shipment and Storage

Listed below are the sampling requirements and holding time for this method.

Matrix	Sample Container	Min. Sample Size	Preservation	Holding Time	Reference
Water	1 L amber *	1 L amber *	>0.0℃ but ≤6.0℃, pH to <2 with HCl or H_2S0_4	28 days	40 CFR Part 136

* Smaller sample containers may be used, but RLs will be affected.

8.1 Sample bottles are pre-preserved using 5 mL of 1:1 HCl or 5 mL of 1:1 H_2SO_4 for a 1 L sample. This should be sufficient to adjust the sample pH to <2. The sample pH must be confirmed prior to extraction.

8.2 Collect approximately one liter of representative sample in a glass bottle following conventional sampling practices, except that the bottle must not be pre-rinsed with sample before collection. To allow for potential QC failures, it is recommended that additional sample aliquots be collected. To allow for MS and/or MSD analysis, collect a 2nd and/or 3rd aliquot for at least one sample. When collecting additional aliquots, either collect simultaneously in parallel, if possible, or collect as grab samples in rapid succession.

8.3 The high probability that extractable matter may adhere to sampling equipment and result in measurements that are biased low precludes the collection of composite samples for determination of oil and grease. Therefore, samples must be collected as grab samples. If a composite measurement is required, individual grab samples collected at prescribed time intervals must be analyzed separately and the concentrations averaged. Alternatively, samples can be collected in the field and composited in the laboratory. For example, collect four individual 250-mL samples over the course of a day. In the laboratory, pour each 250-mL sample into a 1 Liter pre-preserved Glass Bottle, rinse each of the four bottles (and caps)

sequentially with 30 mL of n-hexane, and use the 30 mL of n-hexane for the extraction.

8.4 If a sample is known or suspected to contain greater than 500mg/L of extractable material, collect a smaller volume of sample (the volume required will depend upon the estimated amount of extractable material) in another glass bottle. Add a proportionately smaller amount of HCl or H_2S0_4 solution to the smaller sample for preservation.

9.0 Quality Control

9.1 The following quality control samples are prepared with each batch of samples**.**

Quality Controls	Frequency	Control Limit[1]	
		HEM	SGT-HEM
Laboratory Control Sample (LCS)	1 per batch of 20 samples or less	78-114% recovery	64-132% recovery
Method Blank (MB)	1 per batch of 20 samples or less	< RL	< RL
Matrix Spike (MS)	1 per batch of 20 samples or less	78-114% recovery	64-132% recovery
Matrix Spike Duplicate (MSD)	1 per batch of 20 samples or less	78-114% recovery, RPD <18%	64-132% recovery, RPD <34%

[1]Control Limits are method specified and are maintained in LIMS

[2]The MS/MSD parent sample is randomly selected, unless specifically requested by a client.

9.2 Balance check: criteria for 2mg weight check is ±10%. Criteria for 1g weight check is ±0.5%.

9.2.1 If the balance check is outside of acceptance criteria, do not begin weighing pans. Clean the balance pan, recalibrate the balance and check the required weights again.

9.3 The Method Blank is 1 L of laboratory reagent water added to a pre-preserved bottle and taken through the same extraction and analysis process as the samples in the batch. One MB is prepared along with each batch of 20 or fewer samples. MB must have a residue < 5 mg/L, and should have residue below the current MDL. Sample results will be qualified on the final report for MB's with results above the MDL.

9.3.1 It is not permissible to use blank correction on sample results.

9.3.2 Samples associated with method blanks, which fail the acceptance criteria, must be re-prepared and reanalyzed with an acceptable blank, unless:

- Sample results are non-detect – in which case results may be reported using the "Method Blank – Report, ND" NCM.

- Sample results are greater than 10 times the concentration seen in the blank – in which case results may be reported using the "Method Blank – Report, 10X" NCM.

9.3.3 If there is insufficient sample to reanalyze, inform the project manager of the blank contamination and report results using the "Method Blank – Insufficient Sample" NCM to document the failure.

9.4 The LCS is prepared along with each batch of 20 or fewer samples in the same manner as the Method Blank, with 10mL of spike solution added as in section 7.7. Results must the control limits given in the QC table above.

9.4.1 Samples associated with a LCS, which fails the acceptance criteria, must be prepared and analyzed again with an acceptable LCS unless the LCS recovery is above the control limit, and the associated sample is non-detect. Non-detect results may be reported along with the "LCS/LCSD - %R High" NCM.

9.4.2 If there is insufficient sample volume to repeat the analysis, inform the project manager of the blank contamination and report results using the "LCS/LCSD – Insufficient Sample" NCM to document the failure.

9.5 A minimum of a Matrix Spike (MS) analysis must be performed with each analytical batch of 20 or fewer samples. If there is sufficient volume provided, a Matrix Spike Duplicate (MSD) shall also be included. If insufficient sample is available to prepare a MS, this must be documented with the "MS/MSD – Insufficient Volume" NCM.

9.5.1 If the MS (or MSD) does not meet the acceptance criteria given in the QC table above, evaluate the batch QC and parent sample result.

- If the batch LCS has acceptable recovery, results are reported using the "MS/MSD - %R, LCS Pass" NCM.
- If the parent sample concentration is greater than 4x the spiked amount, the MS recovery cannot be accurately calculated, and the "MS/MSD – High Targets" NCM should be used to document this.

9.6 If sample reanalysis due to QC failure will be past the holding time, inform the project manager of the QC failure and obtain client instructions on how to proceed. The decision on whether to report the original result or perform reanalysis past the holding time must be documented in the case narrative.

9.7 The cleanliness of the silica gel (see section 7.6) must be documented for each lot prior to use.

9.8 Each time a modification is made to this written procedure, including types of equipment used, the laboratory must repeat the initial demonstration of capability and MDL study. (See requirements in section 12.)

10.0 Procedure

10.1 Calibrate the analytical balance at 2 mg and 1000 mg using class "S" weights before and after weighing each batch of samples. (See section 9.2.)

10.2 Allow the samples to warm to room temperature before beginning. (However, do not leave samples on the bench for more than 4 hours.)

10.3 Verify that the pH of the sample is less than 2 using the following procedure:

10.3.1 Dip a glass stir rod into the well-mixed sample.

10.3.2 Withdraw the glass stir rod and allow a drop of sample to fall on a pH strip. Record the sample pH on the TALS worksheet.

10.3.3 As some oil and grease may adhere to the stir rod, rinse the stir rod with hexane and collect into the funnel for filtering the extract into the final collection vessel. Phase separation filter paper must be used so that any water rinsed off by the hexane does not end up in the evaporating dish.

10.3.4 Use a new stir rod for each sample to avoid cross-contamination.

10.3.5 If the sample is at neutral or greater pH, add 5-6 mL of 6N HCl or H_2SO_4 solution or other appropriate amount to adjust the pH of the 1 L sample to < 2. Document the final pH on the TALS worksheet if the sample pH requires adjustment.

10.4 Weigh Disposable Evaporation Pans using an analytical balance and record the weights on the TALS worksheet. Always handle pans with tongs or gloves. Do not touch the pans with bare fingers, or oils from you skin may add weight to the pan.

10.5 Assemble a UCT ENVIRO-CLEAN® Oil and Grease Cartridge Extraction Station and mount a collection chamber on each active port.

10.6 Mount the cartridge and wash the sides with approximately 10 mL of hexane. Allow the cartridge to soak in the hexane for 1 minute. Draw the hexane through the cartridge using the vacuum pump and discard the hexane as waste. Repeat two more times. Draw full vacuum through the cartridge for 2 minutes to remove all the hexane.

10.7 Add 10 mL of methanol to the cartridge and slowly draw the methanol through the cartridge leaving a layer on the surface of the cartridge. **Do not let the sorbent dry out.** Soak for one minute then add 30 mL of DI water to the cartridge. Draw the water through the cartridge to waste.

10.7.1 **Do not allow the sorbent to completely dry before adding the sample**, otherwise repeat steps 10.6 and 10.7.

10.8 Mark the meniscus of the water on the sample bottle. For the LCS and MS/MSD aliquots, spike each in the bottle with the Spiking Standard (Refer to Section 7.7). Mix well.

10.9 Add the 1 liter water sample directly to the cartridge and draw through under full vacuum. This may take several minutes for complete flow through the cartridge depending upon the level of solids in the sample. Use a bottle holder on top of the cartridge if necessary to hold the upside-down bottle securely.

10.9.1 If very high solids are present, add glass wool to the cartridge prior to adding the sample to prevent clogging and achieve good flow. The glass wool must be thoroughly rinsed with hexane before use.

10.10 After the entire sample has filtered, allow the cartridge to dry under full vacuum for 10 minutes to remove excess water. Remove any water remaining in the bottom support of the cartridge with a paper towel. Do not touch the inside of the cartridge.

10.11 Rinse the sample bottle with 10 mL of hexane. Add the hexane to the cartridge, rinsing the sides of the cartridge and the bottle holder, if used. Soak for 3 minutes. Slowly draw the hexane through the cartridge and into the collection vial. Do not allow the vacuum to continually blow on the extract.

10.12 Immediately repeat step 10.11 two more times using 10 mL of hexane.

10.13 Fill the rinsed sample bottle to the meniscus marking, and measure the volume contained using a 1 Liter, class A, graduated cylinder. Record the sample volume on the batch worksheet.

10.14 Add another 10 mL of hexane to the cartridge, rinsing the bottle holder. Allow the cartridge to soak for 3 minutes. Draw the hexane through the cartridge. The total volume of the extract will be about 35 mL.

10.15 Remove the collection vial from the manifold and cover with a screw cap.

10.16 Place a piece of phase separation filter paper into a filter funnel. Rinse three times with hexane and dispose of the rinsate.

10.17 Filter the extract through phase separator filter paper into a pre-weighed 70 mL evaporation pan. Rinse the collection vial and filter paper twice with approximately 5 mL portions of hexane.

10.18 Set the Speedvap to 50^{o}C. Place the evaporating pans into the Speedvap and evaporate to near dryness, visibly. (Evaporating to total dryness may also remove some of the lighter hydrocarbons from the residue.)

10.19 Remove the pans from the Speedvap, and place them in a desiccator for at least one hour.

10.20 Weigh the pans on an analytical balance and record the weights to the nearest 0.1 mg on the TALS worksheet.

10.21 Repeat the cycle of desiccating for 1 hour and weighing until the sample weight loss is < 4% for the previous weight or less than 0.5 mg, whichever is less. If pan weight is not within 0.5 mg, put the sample back in the desiccator for 1 hour and perform a third weighing.

10.22 If only HEM (Oil & Grease) is required to be reported, proceed to result calculation in section 11.2. If SGT-HEM (TPH) is also required, continue with section 10.23.

10.23 SGT-HEM Determination:

If the HEM result is less than the SGT-HEM reporting limit (or MDL), the analyst may report SGT-HEM as less than the reporting limit and stop at this point. SGT-HEM should always be less than or equal to HEM.

10.23.1 Rinse the residue from the HEM determination into a suitable glass container with approximately 40 mL of hexane. This re-dissolved HEM is referred to as “the extract”.

10.23.2 Add 3.0 g of silica gel for every 100 mg of HEM in the extract up to a maximum of 30 grams of silica gel (maximum of 1000 mg of HEM).

- If the amount of silica gel needed exceeds 30 grams, then only process a portion of the extract. For example- if the amount of silica gel needed is calculated to be 60 grams, then use ½ of the extract. Account for this “dilution” in the final calculation for SGT-HEM.

For example: 6.4294 g Residue x 1000 = 6429.4 mg Residue

Based on the maximum concentration of 30 g of silica gel per 1000 mg of HEM a 10X dilution is done on this sample to bring the sample within range, resulting in 642.94 mg of Residue.

Then use 3 g of silica gel per 100 mg of HEM as follows:

642.94 mg/100 mg = 6.4294 mg HEM

6.4294 mg x 3 g silica gel = 19.2882 or 19.3 g of silica gel

So a 10X dilution would need approximately 19 g of silica gel

- The HEM in the extract should be rounded up to the next 100 mg. For example, if the HEM is 735 mg, the amount of silica gel added should be based on 800 mg or 24 grams of silica gel (3 g. x 8).

10.23.3 Shake or stir the sample flask for 15 minutes.

10.23.4 Filter with phase separator paper into a previously weighed 70 mL evaporation pan. Rinse the flask, silica gel and filter paper with several small amounts of hexane to complete the transfer.

10.23.5 Repeat steps 10.18 through 10.21.

10.23.6 Determine the SGT-HEM concentration using the equation in section 11.2.

11.0 Calculations / Data Reduction

11.1 **LCS % Recovery** = $\frac{\text{observed concentration}}{\text{known concentration}} \times 100$

Note: the spike concentration for SGT-HEM is half of the HEM concentration due to the removal of stearic acid during the silica gel treatment.

11.2 **HEM or SGT-HEM (mg/L)** = $\frac{[\ A - B\ ] \times 1{,}000{,}000 \times DF}{\text{mL of sample}}$

Where:
A = final pan weight in grams.
B = initial pan weight in grams.
DF = Dilution factor (= 1 if no dilution performed)

11.3 MS/MSD $\%\ Spike\ Recovery\ (\%R) = \frac{SSR - SR}{SA} \times 100$

where:
SSR=Spiked Sample Result
SR=Sample Result
SA=Spike Added

11.4 Relative Percent Difference (RPD) between the MS and MSD (or LCS/LCSD):

$$RPD = \frac{|Conc.1 - Conc.2|}{(Conc.1 + Conc.2)/2} \times 100$$

Where: Conc. 1 and Conc. 2 are the concentrations (mg/L HEM or SGT-HEM) in the MS and MSD samples, respectively.

Note: the spike concentration for SGT-HEM is half of the HEM concentration due to the removal of stearic acid during the silica gel treatment.

12.0 Method Performance

12.1 The supervisor has the responsibility to ensure that an analyst who has been properly trained in its use and has the required experience performs this procedure. The training documentation will be forwarded to QA for inclusion in the training files. DOCs will be documented for each analyst in the training file.

12.2 **Demonstration of Capabilities(DOC)**

12.2.1 This requires the analysis of four LCS samples. The LCS sample is a well-characterized, laboratory-generated sample used to monitor method performance, which should contain the analyte(s) of interest. The results of the initial demonstration study must be acceptable before analysis of samples under this SOP may begin. Four aliquots of the LCS are prepared and analyzed using the procedures detailed in this SOP.

12.2.2 Recovery of each LCS standard analyzed as part of the IDOC must meet recovery limits of 83-101% for HEM and 83-116% for SGT-HEM. Precision between the four standards must be ≤ 11%RSD for HEM and ≤ 28%RSD for SGT-HEM.

12.2.3 Annually, a Continuing Demonstration of Capability must be documented for each analyst performing this method, using 4 consecutive batch LCS's. The LCS data may come from a single batch or multiple batches. LCS recovery limits listed in Table 9.1 must be met for all points. The %RSD of the set must meet precision criteria of the IDOC given in section 12.2.2.

12.3 **Method Detection Limit Study (MDL)**

12.3.1 A Method Detection Limit (MDL) study, as described in the Detection Limits SOP PT-QA-007, must be performed initially and any time a significant change is made to the analytical system. The MDL must be evaluated at least every 12 months.

12.3.2 The calculated MDL for HEM and SGT-HEM from the MDL study must be ≤ 1.4 mg/L, or ≤ ⅓ the regulatory compliance limit, whichever is greater. Because compliance limits can vary, the laboratory will use 1.4 mg/L as the upper limit for MDL.

13.0 Pollution Control

13.1 It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the "Eurofins TestAmerica Environmental Health and Safety Manual

(CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

14.0 Waste Management

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.2 The following waste streams are produced when this method is carried out.

14.3 Solvent or oily waste. This waste is collected in a waste container identified as "Mixed Flammable Solvent Waste", Waste #3.

14.4 Contaminated filter Paper with Sodium Sulfate, Speed Disc, and aluminum pan. This waste is collected in containers identified as "Lab Trash", Waste #12.

16.0 Method Modifications

16.1 Because a solid-phase extraction is performed; an allowable modification per Method 1664, Revision B, Section 1.7.1.1; the final extract will not have the water content potential from the separatory funnel method. For this reason, sodium sulfate is not added to the funnel for filtration of the extract prior to evaporation. Sodium sulfate was found to produce residues around or above the MDL in sample extracts filtered through it. The extracts are filtered through phase separation paper only.

1. SCOPE AND APPLICATION

1.1 This method determines the presence of free liquids in a representative sample of waste.

1.2 On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department of the Laboratory or Technical Director, and must be documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1 A predetermined amount of sample is placed in a paint filter. If any liquid portion of the sample passes through and drops from the filter within the 5-minute test period, the sample is deemed to contain free liquids.

3. DEFINITIONS

3.1 TALS – Eurofins TestAmerica Laboratory Information Management System

3.2 NCM - Non-Conformance Memo - a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3 Refer to the glossary in the Laboratory Quality Assurance Manual (PT-QA-M-001), current version, for more definitions related to analytical procedures.

4. INTERFERENCES

4.1 Filter media were observed to separate from the filter cone on exposure to alkaline materials. This development causes no problem if the sample is not disturbed.

4.2 Temperature can affect the test results if the test is performed below freezing point of any liquid in the sample. Tests must be performed above the freezing point and can, but are not required to, exceed room temperature of 25°C.

5. SAFETY

5.1 Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001), and this document. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the

method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2 There are no materials used in this method that have a significant or serious hazard rating. A complete list of materials used in the method can be found in the reagents and standards section.

5.3 Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.4 Exposure to chemicals must be maintained as low as reasonably achievable; therefore, unless they are known to be non-hazardous, all samples should be opened, transferred, and prepared in a fume hood, or under other means of mechanical ventilation. Waste containers will be kept closed unless transfers are being made.

5.5 All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 Conical Paint Filter: Mesh number 60 ± 5% (fine meshed size), available at local paint or hardware stores or ordered through Amazon.

6.2 Glass Funnel: If the paint filter, with the waste, cannot sustain its weight on the beaker or in the ring, then a fluted glass funnel or glass funnel with a mouth large enough to allow at least 1 inch of the filter mesh to protrude shall be used to support the filter. The funnel is to be fluted or have a large open mouth in order to support the paint filter yet not interfere with the movement to the beaker of the liquids that passes through the filter mesh.

6.3 Ring stand and ring or tripod

6.4 Glass beaker or disposable plastic cup, 100mL size or larger

6.5 Graduated cylinder, class A, various sizes

6.6 Top-loading Balance, capable of weighing to the nearest 0.01 grams

7. REAGENTS AND STANDARDS

7.1 Not Applicable

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1 Sample Container: Plastic or Glass

8.2 No chemical preservation is required. Samples must be kept at >0°C but ≤6°C during transport and storage prior to analysis.

8.3 No holding time is specified in the method. A six-month holding time is assigned to this test by the lab.

9. QUALITY CONTROL

9.1 A Sample Duplicate is analyzed with every set of 20 or fewer samples.

9.2 Because this procedure does not report numeric results, no %RPD can be applied to the duplicate. The sample and duplicate must agree on the presence or absence of free liquid. If liquid is collected from one and not the other, 2 more portions of the sample must be analyzed.

9.3 No other QC type is applicable to this test.

10. PROCEDURE

10.1 Calibration and Standardization

10.1.1 The balance calibration must be verified daily before using to weigh the sample to be analyzed with weights that bracket the range of use. See SOP PT-QA-012, current version, for balance calibration requirements and procedure.

10.2 A 100 mL or 100g representative sample is required for the test. If it is not possible to obtain a sample of 100 mL or 100g that is sufficiently representative of the waste, the analyst may use larger size samples in multiples of 100 mL or 100g, i.e., 200, 300, 400 mL or g. When larger sample sizes are used, however, analysts shall divide the sample into 100 mL or 100g portions and test each portion separately. If any portion contains

free liquids, the entire sample is considered to have free liquids. If the sample is measured volumetrically, then it should lack major air spaces or voids.

10.3 Assemble test apparatus by placing the paint filter in a ring or top of a beaker that allows sufficient space beneath the filter tip for liquid to be collected without touching the filter. The filter must be supported enough to not fall through the ring, or collapse when filled with the sample.

10.4 Place the appropriate sized, representative sample in the filter. A glass funnel may be used to provide support for the paint filter if necessary. If the sample is of such bulk density that it overflows the filter, then the sides of the filter can be extended upward by taping filter paper to the inside of the filter and above the mesh. Settling the sample into the paint filter may be facilitated by lightly tapping the side of the filter as it is being filled.

10.5 Allow sample to drain for 5 minutes into the beaker. If any liquid portion collects in the beaker during the 5 minute time period, the material is deemed to contain free liquids.

11. CALCULATION / DATA REDUCTION

11.1 No calculations are used for this method

11.2 If no liquid is collected, record the sample weight(s) used in the “Final Amount Value” column on the TALS batch Worksheet. Enter the sample result as “CNF” for Collected No Free liquid (see Figure 1).

11.3 If liquid is collected, record the sample weight(s) used in the “Final Amount Value” column on the TALS batch Worksheet. Enter the sample result as “CFL” for Collected Free Liquid (see Figure 2).

12. METHOD PERFORMANCE

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored by direct observation of the testing.

12.2 Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3 MDLs are not performed for this procedure.

13. POLLUTION CONTROL

13.1 This method does not contain any specific modifications that serve to minimize or prevent pollution.

13.2 It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention."

14. WASTE MANAGEMENT

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001 (Waste Collection, Accumulation and Storage). The following waste streams are produced when this method is carried out:

14.1.1 Solid materials (gloves, paper products) go into waste stream #12 Lab Trash.

SOP # with Revision: PT-WC-036, Rev. 7
SOP Title: Flash Point by Setaflash (Small Scale) Closed-Cup Apparatus
Method: EPA 1020B, 1020C and ASTM Standard D 3278-96
Amendment Number: 1

Effective Date of Amendment:
Append this form to the front of the SOP copy.

CONTROLLED DISTRIBUTION	
COPY # :	**001**
ISSUED TO :	**Pittsburgh SOP Directory**

The following SOP change is in effect as of the stated date. *This form will remain attached to the referenced SOP until such a time that the SOP is updated, approved, and redistributed, at which time it will become part of the historical SOP record.*

1. Briefly explain the reason for the update: Add information on second order curve which is allowed per method. Update of reference year.

2. Category for SOP Change:

☒ Typographical Corrections (Non-Technical) – Retraining Not Required.

☐ Typographical Corrections (Technical- define below) – Retraining is required.

☐ Procedural Changes (Define Below) – Retraining Required.

3. Summary of Procedure Change (circle to indicate if there are attachments to this form: No / Yes: # pages attached = ___)

Flash Point by Setaflash (Small Scale) Closed-Cup Apparatus
Method: EPA 1020B, 1020C and ASTM Standard D 3278-96

Does this change result in a Method Modification? Yes (No)
If yes, please explain below.

Any method modification will be incorporated into section 16 of the SOP at the next revision.

©COPYRIGHT 2021 TESTAMERICA LABORATORIES, INC. d/b/a EUROFINS TESTAMERICA ALL RIGHTS RESERVED.

1.0 Scope and Application

1.1 This standard operating procedure (SOP) describes the determination of whether a material will or will not flash at a specified temperature. This procedure is used in the characterization of the flash point of liquids, solids, wastes and products.

1.2 On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department of the Laboratory or Technical Director, and documented fully in an NCM that accompanies the analytical batch.

2.0 Summary of Method

2.1 For liquid and wastes, 2 mls of sample, using a plastic transfer pipette, is introduced through a leak proof entry port into the tightly closed small scale tester or directly into the cup, which has been brought to within 3 ^{0}C (5 ^{0}F) below the expected flash point. For solid samples 1 to 5 grams of sample is transferred to the bottom of the cup with minimal exposure to air and tested.

2.2 As a flash / no- flash test, the expected flash point temperature may be a specification (e.g.140 ^{0}F). For specification testing, the temperature of the apparatus is raised to precise temperature of the specification flash point by slight adjustment by Temperature dial. After one minute, a test flame is applied inside the cup and note is taken as to whether the test sample flashes or not. The laboratory uses a set temperature of 140 ^{0}F, unless the project specifies a different temperature.

2.3 The flash point temperature is one measure of the tendency of the test specimen to form a flammable mixture with air under controlled laboratory conditions. It is only one of a number of properties which must be considered in assessing the overall flammability hazard of a material. Flash point is used in shipping and safety regulations to define *flammable* and *combustible* materials. One should consult the particular regulation involved for precise definitions of these classifications.

3.0 Definitions

3.1 Flash point – the lowest temperature at which application of an ignition source causes the vapors of a specimen of the sample to ignite under specified conditions of the test. The test specimen is deemed to have flashed when a flame appears and instantaneously propagates itself over the entire surface of the test specimen.

3.2 TALS – TestAmerica Laboratory Information Management System

3.3 NCM- Non-Conformance Memo - a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.4 Refer to the glossary in the Laboratory Quality Assurance Manual (PT-QA-M-001), current version, for general laboratory definitions.

4.0 Interferences

4.1 In order to eliminate contaminates from the test cup, it must be cleaned prior to being utilized. Clean cup with DI water after soil, solid or inorganic liquid analysis. Clean with acetone then DI water after organic sample analysis.

4.2 In certain mixtures, a non-flammable component of the sample may make inert the vapor space above the liquid, thus preventing a flash. Under this condition, the flash point is masked (no distinct flash as defined in section 3.1 is observed) resulting in the reporting of incorrectly high flash point or no flash point. **Continued heating and testing of such a mixture may represent a potential fire hazard, if not recognized.** Analysts should not perform this test unsupervised until they are experienced with sample reactions.

5.0 Safety

Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.1 Specific Safety Concerns or Requirements
In the event a sample ignites in the test apparatus do not attempt to remove the sample. Turn off the apparatus and flame. The flame should go out when the cup is closed. If this does not happen the flame may be extinguished by covering the sample with a non-flammable material. After the apparatus has cooled the sample may be removed.

5.2 Consult the SDS for the liquefied propane gas used prior to beginning work with this SOP.

Material	Hazards	Exposure Limit (1)	Signs and Symptoms of Exposure
Liquefied Propane gas	Extremely flammable	TWA: 1800 mg/m^3 8 hours, 1000 ppm 8 hours	No known significant effects or critical hazards
(1) Exposure limit refers to the OSHA PEL, 2/2013			

6.0 Equipment and Supplies

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 Setaflash closed tester

6.2 Thermometer, 20-230°F with 1° graduations.

6.3 Lighter

6.4 Plastic transfer pipettes

6.5 Timer

6.6 Wooden spatulas for solids

7.0 Reagents and Standards

7.1 Liquefied Propane gas

8.0 Sample Collection, Preservation, Shipment and Storage

Matrix	Sample Container	Min. Sample Size	Preservation	Holding Time
Liquids	Glass jar / PTFE seal	250 mL	Cool, >0.0°C but ≤6.0°C	28 Days*
Solids	Glass jar/ PTFE seal	250 g	Cool, >0.0°C but ≤6.0°C	28 Days*

*No Holding Time is specified by the referenced methods or 40 CFR Part 136.3

8.1 Sample containers should be between at least 60% full and tightly sealed to preserve sample integrity.

8.2 No chemical preservation is required or appropriate.

9.0 Quality Control

9.1 The following quality control samples are prepared with each batch of samples:

Quality Controls	Frequency	Control Limit
Sample Duplicate	1 in 20 or fewer samples	Flash / No-Flash agreement

9.2 The thermometer has its calibration verified against a NIST thermometer annually. Calibration is documented in the thermometer calibration logbook. The calibration correction factor is noted on the thermometer and must be applied to all temperature measurements. Refer to SOP PT-QA-008 for details of thermometer calibration verification and correction factor requirements.

9.3 Anomalous situations occurring during sample analysis must be documented on the bench sheet and non-conformance memo must be issued if necessary.

10.0 Procedure – Method A – Flash/No Flash

10.1 Ensure that test cup is clean, dry and at room temperature before proceeding.

10.2 Switch the heater on, if not already at standby. To rapidly approach the specification flash temperature of the material under test, turn the heater dial fully clockwise causing red light to glow. The temperatures can be preset to 140 °F (or project specified temperature). When the thermometer indicates a temperature of about 3°C (5°F) below the specification or target flash point temperature, reduce the heat input to the test cup by slowly turning the heater control dial counter clockwise until signal light goes out. Make sure to apply the thermometer's correction factor to all readings.

10.3 After the test cup temperature has stabilized at the specification or target flash point, using transfer pipette, place the sample being tested into the test cup.

10.4 Set the timer for 1 min.

10.5 Open the gas control valve and light the pilot and test flames. Adjust the test flame size to 4mm, with pinch valve. A larger flame may obscure a sample flash. See Attachment 2 for flame size reference.

10.6 After one minute, a test flame is applied inside the cup and note is taken as to whether the test sample flashes or not.

10.7 Electronically record whether, it flashes or not and report either < 140°F or > 140°F in TALS (see Attachment 1 for TALS Screenshots).

10.7.1 If the project specifies a temperature other than 140°F, samples are analyzed at that temperature and results shall be reported as < or > the specified temperature, and the temperature difference detailed in an observation NCM.

10.8 If the sample flashes, repeat the test once, using a fresh portion of sample, to verify the result.

10.8.1 If the second portion of sample does not flash, repeat the analysis a third time to confirm flash or no flash for the sample, and narrate that a third portion was required.

10.9 Any anomalies seen during the analysis shall be documented using the Anomaly NCM for inclusion in the case narrative.

11.0 Calculations / Data Reduction

11.1 No calculations are performed for this test.

12.0 Method Performance

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. On-going performance is monitored through internal QC and outside performance evaluation samples.

12.2 Demonstration of Capabilities can only be performed through observation of the test by another trained analyst or supervisor.

12.3 MDLs are not performed for this procedure.

13.0 Pollution Control

13.1 It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

14.0 Waste Management

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001.

14.2 Waste from samples that flash are placed into Mixed Solvent Waste, Waste #3.

©COPYRIGHT 2020 TESTAMERICA LABORATORIES, INC. d/b/a EUROFINS TESTAMERICA ALL RIGHTS RESERVED.

1. SCOPE AND APPLICATION

1.1. This SOP is applicable to the determination of total suspended solids and volatile suspended solids using gravimetric techniques. This SOP is based on the residue methods contained in EPA MCAWW and Standard Methods for the Examination of Water and Wastes (SM).

1.2. This SOP is applicable to drinking, surface, and saline waters and domestic and industrial wastes.

1.3. The Total Suspended Solids (TSS), or Non Filterable Residue, analysis protocol is based on SM 2540D.

1.4. The Volatile Suspended Solids (VSS) analysis protocol is based on EPA Method 160.4 and SM 2540E.

1.5. The methods cover a practical range of 2 mg/L to 20,000 mg/L.

1.6. The reporting limit is 2 mg/L for TSS and VSS, for a 1000mL sample. Analyzing smaller sample volumes will result in proportionally higher reporting limits.

1.7. On occasion clients may request slight modifications to this SOP. Any modifications must be approved by the QA department of the Laboratory of Technical Director, and documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1. Total Suspended Solids (TSS): A well-mixed sample is filtered through a pre-weighed glass fiber filter with a pore size of 2.0µm (or smaller). The residue on the filter is dried to constant weight at 103 -105°C. The increase in weight over that of the pre-weighed filter represents the TSS content. The filtrate from this procedure may be used for TDS determination. The filter from this procedure may also be used for VSS analysis.

2.2. Volatile Suspended Solids (VSS): The residue obtained from the determination of total suspended solids is ignited at 550°C. VSS is determined from the weight loss after ignition.

2.3. Total Dissolved Solids may be performed at the same time, using the filtrate from the TSS filtration. Refer to SOP PT-WC-045 for details of this analysis.

3. DEFINITIONS

3.1. TALS – TestAmerica Laboratory Information Management System

3.2. NCM – Non-Conformance Memo - a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3. Refer to the glossary in the Laboratory Quality Assurance Manual (PT-QA-M-001), current version.

4. INTERFERENCES

4.1. Method interferences may be caused by contaminants, reagents, glassware, and other sample processing hardware. All these materials must be routinely demonstrated to be free from interferences under the conditions of analysis by running method blanks.

4.2. Non-homogeneous samples may give erroneous results. Samples should be mixed as thoroughly as possible before removing an aliquot for analysis.

4.3. Non-representative particulates such as leaves, sticks, and other detritus should be excluded from the sample if it is determined that their inclusion is not desired in the final result. The presence/removal of these artifacts should be noted on the benchsheet.

4.4. Samples containing large amounts of solids may filter slowly. Prolonged filtration times resulting from filter clogging may produce high TSS results due to increased colloidal materials captured on the clogged filter. Analysis volumes should be reduced for such samples.

4.5. Oil and grease in the samples will cause unreliable results due to difficulty in drying to constant weight. Floating oil and grease, if present, should be included in the sample and dispersed by a blender device before aliquoting.

4.6. Filtration apparatus, filter material, pre-washing, post-washing, and drying temperatures are specified because these variables have been shown to affect the results.

4.7. The temperature at which the residue is dried has an important bearing on the results because weight losses due to volatilization of organic matter, mechanically occluded water, water of crystallization, and gases from heat-induced chemical decomposition, as well as weight gains due to oxidation, depend on temperature and time of heating.

4.8. Each sample requires close attention to desiccation after drying. Minimize opening the desiccator because moist air enters. Some samples may be more hygroscopic than those used as the desiccant and may take absorb additional water from the air as they cool.

4.9. Too much residue on the filter will crust over, entrapping water that will not be driven off during drying. Total residue must be limited to 200 mg (0.200g).

4.10. For samples high in dissolved solids, thoroughly wash the filter to ensure removal of dissolved material prior to TSS determination.

4.11. The volatile solids tests are subject to many errors due to the loss of water of crystallization, loss of volatile organic matter prior to combustion, incomplete oxidation of certain complex organics and decomposition of mineral salts during combustion. The results should not be considered an accurate measure of organic carbon in the sample.

4.12. Oils from hands can be transferred to the filters, causing a positive interference with these analyses. Handle filters only with forceps.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S manual (PT-HS-001), and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2. Oily samples or those that contain volatile chemicals may ignite during this procedure. In the case of a fire, the muffle should be turned off and allowed to cool before the sample can be removed and put under a hood.

5.3. Always use tongs, forceps or heat resistant gloves when placing filter pans in or removing them from ovens. Extra care should be used when using a muffle furnace, as temperatures are extremely high. Gloves designed for dealing with extreme temperatures must be used when handling any sample container that has been in a muffle furnace.

5.4. There are no materials used in this method that have a significant or serious hazard rating. A complete list of materials used in the method can be found in the reagents and

materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

5.5. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.6. Exposure to chemicals must be maintained as low as reasonably achievable; therefore, unless they are known to be non-hazardous, all samples should be opened, transferred, and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.7. All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1. Analytical balance capable of weighing to 0.0001 g

6.2. Vacuum filtration apparatus

6.3. Vacuum pump equipped with moisture trap

6.4. Glass fiber filter disks, 47 mm, pore size $\leq$ 2µm, without organic binder - Whatman 934-AH, pre-cleaned and pre-weighed, or ProWeigh filters from Environmental Express.

6.4.1. If VSS analysis is to be performed, Environmental Express Proweigh Filters (part # F93447VOL) are used. Glass fiber filter disks, 47 mm, pore size $\leq$ 2µm, without organic binder, pre-cleaned and dried at 550^{o}C and pre-weighed

6.4.2. If pre-cleaned filters are not used, the preparation steps in section 10.3.1.2 must be used prior to filtering samples.

6.5. Desiccators providing sufficient space for storage of samples in process separate from filters and evaporating dishes

6.6. Desiccant containing a color indicator of moisture concentration or an instrumental indicator

6.7. Drying oven set at 103 -105°C

6.8. Muffle furnace set at 550°C ± 50°C

6.9. Thermometers, NIST traceable

6.10. Graduated cylinders, to deliver (TD), assorted sizes, Class A

6.11. Aluminum weighing dishes large enough to hold a 47 mm filter - (Pre-weighed filters are purchased already in Aluminum dishes.)

6.12. Forceps

6.13. Zetex gloves or other gloves capable of providing protection at 550°C

6.14. Wide-bore serological volumetric pipettes

7. REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard.

7.1. Reagent water - Deionized water, with conductance <1 umhos/cm – to be used for blanks and rinses

7.2. The LCS standard solution is commercially purchased. The true value varies from lot to lot when received from the manufacturer and the calculation is adjusted accordingly by the laboratory. The standard is received with a certificate of analysis with the true value listed on it and is retained by the laboratory.

7.2.1. If the solution needs to be made by the laboratory the procedure is as follows: LCS solution (500 mg/L TSS and TDS, 1000 mg/L TS): Place 500.0 mg of diatomaceous earth (infusorial earth or celite 545) and 500 mg sodium chloride into a 1000 mL volumetric flask and dilute to volume with deionized water. Mix well. Prepare fresh every three months.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1. Samples should be collected in either plastic or glass bottles. No chemical preservation is appropriate.

8.2. Samples must be stored at >0.0℃ but ≤6.0℃ to minimize microbiological decomposition of solids. Bring samples to room temperature before analysis.

8.3. To meet method SM2540D requirements, sufficient sample volume, **up to 1 L**, must be filtered to produce at least 2.5mg (0.0025g) of final residue on the filter.

8.3.1. Smaller samples sizes may be used for samples that are high in solids. Historical data or visual inspection may be used to choose a different sample size for initial analysis, as long as the minimum (2.5mg or 0.0025g) and maximum (200mg or 0.200g) limits are met.

8.4. Holding time for TSS and VSS determination is 7 days from the date of sampling to begin the analysis.

9. QUALITY CONTROL

The TestAmerica QC Program document (PT-QA-021) provides further details of the QC and corrective action guidelines presented in this SOP. Refer to this document if additional guidance is required.

9.1. Method Blank (MB): One method blank must be processed with each batch of 20 or fewer samples. The method blank consists of 1L of reagent water that is carried through the entire analytical procedure, including filtration as applicable. The method blank is used to identify any system and process interferences or contamination of the analytical system that may lead to the reporting of elevated analyte concentrations or false positive data. Blank results must be less than the RL. If the MB result is above the RL, all associated samples must be reanalyzed unless one of the following conditions exists.

- If a Blank result is above the RL, but solids are not detected above the RL in the associated samples, the data may be reported with qualifiers and using the “Method Blank – Report, ND” NCM.

- If the sample concentrations are greater than 10x the concentration seen in the MB, results may be reported with qualifiers and using the "Method Blank – Report, 10X" NCM

9.1.1. High blank results indicate contamination. Make sure the filtering apparatus is clean before repeating the analysis.

9.1.2. If MB results are negative (filter weighs less after analysis), this indicates that the balance was not operating correctly or the filter/weighing dish was not completely dry when the initial weights were measured. If MB results are below the negative RL (a change of -0.0025g for example), all samples with concentrations <10X the RL should be reanalyzed if possible. If reanalysis is not possible, the negative blanks and possible negative bias for the sample results must be narrated using the "Other – Deficiency" NCM.

9.2. Laboratory Control Sample (LCS): One LCS must be processed with each batch of 20 or fewer samples. The LCS must be carried through the entire analytical procedure. The LCS is used to monitor the accuracy of the analytical process. On-going monitoring of the LCS results provides evidence that the laboratory is performing the method within acceptable accuracy and precision guidelines.

9.2.1. No LCS is available for volatile residue procedures.

9.2.2. Refer to Section 7.2.1 for instructions on how to prepare the LCS solution, unless using a purchased standard. The LCS analysis volume must be calculated to produce a final residue between 2.5 and 200mg (0.0025 and 0.20g).

9.2.3. The LCS percent recovery must be within 80 -120% of the true or certified value.

9.2.4. If LCS recovery is outside the control limits, all associated samples must be reanalyzed with an acceptable LCS, unless the original LCS recovery is high and samples results are <RL.

9.2.4.1. If reanalysis is not possible due to limited sample quantity or holding time considerations, the project manager must be notified so that the client can be informed. Results reported associated with a failed LCS must be reported with the appropriate result qualifier and the failure narrated through the appropriate NCM:

- For high LCS recovery and associated samples <RL, use "LCS/LCSD - %R High".
- If samples are reanalyzed due to failed LCS, and the reanalysis occurs past the holding time, use "LCS/LCSD - %R, RX/RA Batch, Outside".
- If there is insufficient sample volume to perform a reanalysis, use "LCS/LCSD – Insufficient Sample".

9.2.5. Poor LCS results are usually the result of contamination or poor mixing. Make sure to shake the LCS and all samples very well before pouring out the portion to be filtered or analyzed. Do not allow the sample to settle in the graduated cylinder.

9.3. Duplicate (D): A duplicate sample analysis is required with every 10 samples or less for all methods.

9.3.1. Sample and Duplicate results must agree within 10%RPD The failure of the sample duplicates to meet precision criteria must be addressed in the case narrative.

9.3.2. Make sure to shake all samples very well before pouring out each portion to be filtered or analyzed to improve homogenization and precision. Do not allow the sample to settle in the graduated cylinder before analyzing.

9.3.3. On-going method precision is documented using LCS control charting.

10. PROCEDURE

10.1. Calibration and Standardization

10.1.1. Proper balance operation will be verified daily or prior to sample analysis by following the balance calibration SOP, PT-QA-12. Analytical balance calibration must be verified at least every 24 hours, and prior to using the balance each day. Weights used for calibration verification, prior to initial and read-back weighings, are documented in the TALS batch information.

10.1.1.1. For TSS and VSS, balances are verified using 2mg, 0.300g, 10g and 120g weights.

10.1.1.2. Balance reading for the 2mg weight must be 0.0018g - 0.0022g; for the 0.300 g weight must be 0.2995g – 0.3005 g; for the 10g weight must be 9.9900g – 10.0100g and for the 120g weight must be 119.88000g – 120.1200g. If any reading falls outside these limits, the balance must be recalibrated and the verification performed again with all weights in the group.

10.1.2. Oven temperature must be checked daily and recorded in the oven temperature logbook. Oven temperature must be kept between 103-105^{o}C. Volatile Suspended Solids are ignited in the muffle furnace at 550 $\pm$ 50^{o}C. The temperature of the muffle furnace used for volatile residues analyses is documented at the time of use.

Note: If oven temperatures are not within the required range, the temperature setting must be adjusted to bring it within range. The drying/burn time for the samples does not begin until oven or furnace is within the required temperature range.

10.2. Procedure

10.2.1. Any variation in procedure shall be completely documented using a Nonconformance Memo and must be approved by a Supervisor or Manager. If contractually required, the client shall be notified.

10.2.2. All samples are to be electronically checked out of sample control with the TALS internal chain of custody (ICOC) program.

10.2.3. Proper sample identification is extremely important in any analytical procedure. Labeling of filters holders must be done in a manner to ensure connection with the proper sample. Labeling must be done in a way that will not be compromised by the heat used. For VSS, the sample ID is pressed into the aluminum pan.

10.2.4. Non-representative particulates such as leaves, sticks, and other detritus should be excluded from the sample if it is determined that their inclusion is not desired in the final result. The presence/removal of these artifacts should be noted on the TALS Worksheet Notes or Batch Information Comments.

10.2.5. If samples are visibly oily, this should be noted on the TALS Worksheet Notes or Batch Information Comments.

10.2.6. If there is limited sample volume or high solids content, smaller amounts of sample may need to be processed than detailed in the following sections. This occurrence must be noted on the TALS Worksheet. Reporting limits are adjusted according to the actual sample volume used.

10.2.7. All weights are recorded to the nearest 0.1mg directly from the balance into the TALS Worksheet using balance upload. If the balance upload is not working, the weights are recorded in the Wet Chemistry Raw Data Logsheet for transfer to the TALS Worksheet. If the manual Logsheet is used, it must be scanned to a pdf and attached to the TALS batch as raw data.

10.2.8. Prepare TALS analytical batches prior to beginning analysis, as the batch must be available to upload initial weights and record sample volumes used.

10.2.9. Scan the barcode on the filter's pan for pre-weighed filters. This will upload both the pan ID and the filter weight into the "Dish" column on the TALS Worksheet. Manually enter the filter weight into the "Tare Weight Value" column. (See Figure 4.)

10.3. Total Suspended Solids – SM 2540D

10.3.1. Preparation of Glass Fiber Filter Disc:

10.3.1.1. Prepared and pre-weighed filters are purchased for use under this method. The certificate of analysis is retained for the filters. The filter lot number is documented in the TALS Batch Information. Scan the barcode on the filter's pan to enter the tare weight of the filter into the TALS Batch Worksheet.

- When a new lot/box of pre-weighed filters is opened for use, 5% of the filters are chosen at random, and weighed to confirm that the weights provided are correct, within 0.0004g. If the filter weight does not agree, that filter is not used. If more than 5 filters checked per box do not agree, the box is not used for analysis.
- For TSS only analysis, use Whatman 934-AH filters or ProWeigh filters from Environmental Express. If VSS analysis is to be performed, use only Environmental Express ProWeight filters.

10.3.1.2. If prepared/pre-weighed filters are not used:

- Place the glass fiber filter discs, one at a time, on the membrane filter apparatus with wrinkled surface side up.
- While vacuum is applied, wash the disc with three successive 20 mL volumes of reagent water.
- Remove all traces of water by continuing to apply vacuum after water has passed through and discard washings.
- Remove filter from membrane filter apparatus and place in a labeled, aluminum weighing dish. Dry the prepared filters in an oven at 103 -105°C for at least one hour.
- If volatile suspended solids (VSS) are to be determined as well as total suspended solids, the filter must be heated at 550 $\pm$ 50^{o}C for 15 minutes.
- Using forceps, remove the pans from the oven and place in a desiccator and cool to room temperature.
- Weigh the cooled filter using an analytical balance to the nearest 0.1 mg. Handle the filters or pan/filter only with forceps. This weight is automatically uploaded into the TALS Worksheet and associated with the TALS sample batch using the Balance Link program (see Figure 4).
- Repeat the drying, cooling, and weighing cycle until a constant weight is obtained or weight loss is less than 0.5 mg.

10.3.2. Selection of Sample Volume

10.3.2.1. For the Method Blank and clean samples, filter 1000mL.

10.3.2.2. If during filtration of this initial volume, the filtration rate drops rapidly or if filtration time exceeds 5 - 10 minutes, a smaller volume of sample should be processed. Sample cannot be poured out of the filtration apparatus once added. If a smaller sample size is needed, the analysis must be started over.

10.3.2.3. If the sample appears high in TSS, start with a sample volume < 100mL. If the sample filters rapidly and no significant residue remains on the filter, more volume can be added. If volumes less than 10 mL are required, measure the sample volume using a wide-bore serological pipette, so as not to exclude larger particles from the sample aliquot.

10.3.2.4. For TSS, a residue of at least 2.5mg must be obtained, or a liter of water must be filtered.

10.3.3. Sample Analysis:

10.3.3.1. Assemble the filtering apparatus, and rinse with DI water.

10.3.3.2. Weigh filter, or scan pre-weighed filter pan, and enter the filter weight into the TALS worksheet. Place the filter in the apparatus, wrinkled surface side up. Pre-wet the filter using a few mL of reagent water and begin suction.

10.3.3.3. Shake the sample vigorously and quantitatively transfer the appropriate volume of the sample to the filter using a graduated cylinder or wide-bore pipette. For samples which are visibly high in TSS or are otherwise slow to filter, filter 25mL at a time until filtration slows. Record the volume of sample filtered (to the nearest mL) on the TALS Worksheet.

Note: If Total Dissolved Solids (TDS) is also required, the filtrate from the TSS analysis may be used. Refer to SOP PT-WC-045 for details of TDS analysis.

10.3.3.4. Remove all traces of water by continuing to apply vacuum after the sample has passed through.

10.3.3.5. With suction on, rinse the graduated cylinder, filter, suspended solids residue, and filter funnel wall with three approximately 10 mL portions of reagent water allowing complete drainage between washings.

10.3.3.6. Remove all traces of water by continuing to apply vacuum for about three minutes after the sample has passed through.

10.3.3.7. Carefully remove the filter from the filter support and transfer back to its aluminum weighing dish.

10.3.3.8. Dry the filter at least one hour at 103 -105°C.

10.3.3.9. Record the date, time, and oven temperature on the TALS Batch Information when the samples are initially placed in the oven and again when they are removed from the oven (see Figure 3).

10.3.3.10. Using forceps, remove the weighing dish from the oven and place in a desiccator.

10.3.3.11. Cool the samples to room temperature in the desiccator. Weigh the filter and upload the weight to the TALS Worksheet (see Figure 4).

10.3.3.12. If the residue is >0.2g (200mg), start the analysis over again with a smaller sample volume. If insufficient volume is available for reanalysis, proceed with the steps below, and narrate that the results were determined from a residue >0.2g. Longer drying times may be required to reach constant weight.

10.3.3.13. Return the samples to the oven for at least another hour, cool in a desiccator, and reweigh. Repeat the drying, cooling, desiccating, and weighing cycle until a constant weight is obtained. Constant weight is considered a weight change < 0.5 mg or < 4% of the previous weight, whichever is less. If constant weight has not been achieved after three cycles of heating, cooling and weighing; document the 3 weights and do not perform any further cycles. Document that only 3 heating cycles were performed using an NCM. The lowest weight of the 3 is used for calculating the final result.

NOTE: All dates, times, temperatures and weights are recorded in the TALS Batch.

10.3.3.14. If volatile suspended solids are to be determined, treat the residue according to Section 10.4.

10.3.3.15. TALS will automatically calculate the sample result from the data entered into the Worksheet. Check the calculations using the formula given in Section 11.1. Use the lowest final weight achieved for calculating TSS.

10.4. Volatile Suspended Solids – 160.4 and SM 2540E

10.4.1. Heat the muffle furnace up to temperature (550 ± 50 °C).

10.4.2. Place the filter from the TSS analysis (Section 10.3.3.) into an aluminum pan that does not have a paper label. Press the sample ID into the pan. Place the pans into the muffle furnace to ignite the residue.

10.4.3. Record the date, time, and muffle furnace temperature in the TALS Batch Information when the samples are initially placed in the oven and again when they are removed from the oven (see Figure 5 or 7).

10.4.4. Heat the samples for at least 20 minutes. Typically, 15 - 20 minutes ignition is sufficient for 200 mg of residue. Because TSS residue is restricted to <200mg, only a single ignition is required for VSS.

10.4.5. Using tongs and heat resistant gloves, remove the weighing dish from the muffle furnace and place in a desiccator and cool to room temperature.

10.4.6. Weigh the cooled pan, and upload the weight into the TALS Batch Worksheet (see Figure 6 or 8).

10.4.7. Return filter to furnace for another 15 minutes. Cool in desiccator. Weigh and upload weight into TALS.

10.4.8 TALS will calculate the final results. Check calculations using the formula given in Section 11.2. Use the lowest final weight achieved for calculating VSS.

11. CALCULATIONS / DATA REDUCTION

11.1. Calculate Total Suspended Solids as follows:

$$\text{Total Suspended Solids, mg / L} = \frac{(A - B) \times 1000}{C}$$

Where: A = weight of filter + residue (mg)
B = weight of filter (mg)
C = volume of sample filtered (mL)

11.2. Calculate Volatile Suspended Solids as follows:

$$\text{Volatile Suspended Solids, mg / L} = \frac{(A - B) \times 1000}{C}$$

Where: A = weight of residue + filter before ignition (mg)
B = weight of residue + filter after ignition (mg)
C = volume of sample (mL)

11.3. The relative percent difference (RPD) of duplicates are calculated according to the following equation:

$$RPD = 100\left[\frac{|DU1 - DU2|}{\left(\frac{DU1 + DU2}{2}\right)}\right]$$

Where: DU1 = Sample result
DU2 = Sample duplicate result

11.4. LCS Percent Recovery

$$\text{LCS Percent Recovery} = \left(\frac{\text{Observed Conc. in LCS}}{\text{True LCS Conc.}}\right) \text{x } 100 \text{ Percent}$$

11.5. If multiple weighing cycles are required, the lowest final sample weight is used for calculating solids content.

11.6. If smaller or larger sample volumes are processed than are specified in the method, the reporting limit must be adjusted accordingly.

11.7. Sample results should be reported according to the following significant figure rules:

Significant Figures	Sample Result
2	< 10
3	≥ 10

12. METHOD PERFORMANCE

12.1. The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2. Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3. MDLs are calculated annually from Method Blank data according to SOP PT-QA-007, and are compared to the Reporting Limit. Results are not reported below the RL.

13. POLLUTION CONTROL

13.1. It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2. This method does not contain any specific modifications that serve to minimize or prevent pollution

14. WASTE MANAGEMENT

14.1. Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001.

14.2. The following waste streams are produced when this method is carried out.

14.2.1. Unpreserved waste samples. This waste is disposed down a lab sink.

14.2.2. Aluminum weighing tins, contaminated filter and filter residue generated by the analysis. This waste is disposed of in trashcans with the building trash.

16. METHOD MODIFICATIONS

16.1. Samples are not taken through the drying, cooling, and weighing cycle more than three times. If the sample fails to reach constant weight within three cycles, this is documented in a Nonconformance Memo and the lowest final weight is used for the calculation.

SOP # with Revision: PT-WC-045 Rev. 4
SOP Title: Determination of Total and Volatile Suspended Solids in Waters and Wastes
Amendment Number: 1

Effective Date of Amendment:
Append this form to the front of the SOP copy.

CONTROLLED DISTRIBUTION	
COPY # :	**001**
ISSUED TO :	**Pittsburgh SOP Directory**

The following SOP change is in effect as of the stated date. *This form will remain attached to the referenced SOP until such a time that the SOP is updated, approved, and redistributed, at which time it will become part of the historical SOP record.*

1. Briefly explain the reason for the update: 40 CFR Part 136 Update of Reference Year

2. Category for SOP Change:

☒ Typographical Corrections (Non-Technical) – Retraining Not Required.

☐ Typographical Corrections (Technical- define below) – Retraining is required.

☐ Procedural Changes (Define Below) – Retraining Required.

3. Summary of Procedure Change (circle to indicate if there are attachments to this form: No / Yes: # pages attached = ___)

15.1. Standard Methods for the Examination of Water and Waste Water, 2011, 2015; Methods 2540D and 2540E, on-line editions

Does this change result in a Method Modification? Yes (No)
If yes, please explain below.

Any method modification will be incorporated into section 16 of the SOP at the next revision.

1. SCOPE AND APPLICATION

1.1. This SOP is applicable to the determination of total dissolved solids and volatile dissolved solids using a gravimetric technique. This SOP is based on the residue methods contained in Standard Methods for the Examination of Water and Wastes (SM), 2011.

1.2. This SOP is applicable to drinking, surface, and saline waters and domestic and industrial wastes.

1.3. The Total Dissolved Solids (TDS), or Filterable Residue, analysis protocol is based on SM 2540C.

1.4. The Volatile Dissolved Solids (VDS) analysis protocol is based on SM 2540E.

1.5. The methods cover a practical range of 10 mg/L to 20,000 mg/L

1.6. The reporting limit is 10 mg/L for TDS and VDS.

1.7. On occasion clients may request slight modifications to this SOP. Any modifications to this procedure must be approved by the QA department or the Laboratory or Technical Director, and documented fully in an NCM that accompanies the analytical batch.

2. SUMMARY OF METHOD

2.1. Total Dissolved Solids (TDS): A well-mixed sample is filtered through a glass fiber filter with a pore size of 2.0µm (or smaller). The filtrate is quantitatively transferred into a preweighed evaporating dish and is evaporated to dryness and then dried to constant weight at 180°C. The increase in weight over that of the empty dish represents the total dissolved solids. The filter from this procedure may also be used for TSS/VSS determination.

2.2. Volatile Dissolved Solids (VDS): The residue obtained from the determination of total dissolved solids is ignited at 550°C in a muffle furnace. The loss of weight on ignition is reported as mg/L volatile dissolved solids.

2.3. Total Suspended Solids may be performed at the same time, using the filter from the TDS filtration. Refer to SOP PT-WC-043 for details of this analysis.

3. DEFINITIONS

3.1. TALS – TestAmerica Laboratory Information Management System

3.2. NCM - Non-Conformance Memo - a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.3. Refer to the glossary in the Laboratory Quality Assurance Manual (PT-QA-M-001) for additional definitions.

4. INTERFERENCES

4.1. Method interferences may be caused by contaminants, reagents, glassware, and other sample processing hardware. All these materials must be routinely demonstrated to be free from interferences under the conditions of analysis by running method blanks.

4.2. Non-homogeneous samples may give erroneous results. Samples should be mixed as thoroughly as possible immediately before removing an aliquot for analysis.

4.3. Samples containing large amounts of suspended solids may filter slowly. Prolonged filtration time and pressure may cause breakthrough of some suspended material into the filtrate. Analysis volumes should be reduced for such samples.

4.4. Oil and grease in samples which permeates the filter will cause unreliable results due to difficulty in drying to constant weight. If present, oil & grease should be included in the sample and dispersed by a blender device before aliquoting.

4.5. Filtration apparatus, filter material, pre-washing, post-washing, and drying temperatures are specified because these variables have been shown to affect the results.

4.6. The temperature at which the residue is dried has an important bearing on the results. Weight losses due to volatilization of organic matter, mechanically occluded water, water of crystallization, and gases from heat-induced chemical decomposition, as well as weight gains due to oxidation, depend on temperature and time of heating.

4.7. Each sample requires close attention to desiccation after drying. Minimize opening the desiccator because moist air enters. Some samples may be more hygroscopic than those used as the desiccant and may take absorb additional water from the air as they cool.

4.8. Highly mineralized waters containing significant concentrations of calcium, magnesium, chloride, and/or sulfate may be hygroscopic and will require prolonged drying, desiccation and rapid weighing.

4.9. Samples containing high concentrations of bicarbonate may require careful and possibly prolonged drying to ensure that all the bicarbonate is converted to carbonate.

4.10. Too much residue in the drying vessel will crust over, entrapping water that will not be driven off during drying. Total residue must be limited to 200 mg (0.200g).

4.11. Some samples may have fine suspended solids that will pass through the glass fiber filter causing high TDS results. If solids are visible in the filtered sample, this must be documented in the batch comments.

4.12. Aluminum pans must not be used for TDS/VDS analyses. Components in some samples may react to form aluminum compounds, causing unreliable results.

4.13. For samples high in dissolved solids, thoroughly wash the filter after the sample has passed through to ensure removal of dissolved material prior to TSS determination, if included.

4.14. The volatile solids tests are subject to many errors due to the loss of water of crystallization, loss of volatile organic matter prior to combustion, incomplete oxidation of certain complex organics and decomposition of mineral salts during combustion. The results should not be considered an accurate measure of organic carbon in the sample.

4.15. Oils from hands can be transferred to the drying vessels or filters, causing a positive interference with these analyses. Handle crucibles, beakers and filters only with tongs or gloves.

5. SAFETY

5.1. Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S manual (PT-HS-001), and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2. Oily samples or those that contain volatile chemicals may ignite during this procedure. In the case of a fire, the muffle should be turned off and allowed to cool before the sample can be removed and put under a hood.

5.3. Always use tongs, forceps or heat resistant gloves when placing sample vessels in or removing them from ovens. Extra care should be used when using a muffle furnace, as temperatures are extremely high. Gloves designed for dealing with extreme temperatures must be used when handling any samples or glassware that has been in a muffle furnace.

5.4. There are no materials used in this method that have a significant or serious hazard rating. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

5.5. Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have been contaminated will be removed and discarded; other gloves will be cleaned immediately.

5.6. Exposure to chemicals must be maintained as low as reasonably achievable; therefore, unless they are known to be non-hazardous, all samples should be opened, transferred, and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.7. All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported immediately to a laboratory supervisor or EH&S coordinator.

5.8. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

6. EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An

item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1. Analytical balance capable of weighing to 0.0001 g

6.1.1. Environmental Express StableWeigh system for use with TDS bags – fitted to balance to remove static from bags before weighing.

6.2. Vacuum filtration apparatus

6.3. Vacuum pump equipped with moisture trap

6.4. Glass fiber filter disks, 47 mm, pore size $\leq$ 2µm, without organic binder - Whatman 934-AH, pre-cleaned and pre-weighed (If pre-cleaned filters are not used, the preparation step in section 10.2 must be used prior to filtering samples.)

6.5. Evaporating dishes, 120 mL, made of porcelain. These must be thoroughly cleaned, rinsed with deionized water, and baked at 180 ± 2°C for at least one hour before use for TDS and baked at 550$\pm$50^{o}C for at least 1 hour for use for VDS. Store prepared dishes in a desiccator.

Note: 150mL glass beakers may also be used for TDS determinations. Glass beakers may not be used for procedures requiring use of a muffle furnace (VDS).

Note: Environmental Express StableWeigh pre-dried and pre-weighed TDS bags (part # TDS100) may also be used for TDS determinations. Bags may not be used for procedures requiring use of a muffle furnace (VDS). At least 2 bags per lot must be checked before use to verify the weights are accurate.

6.6. Desiccators providing sufficient space for storage of samples in process separate from filters and evaporating dishes

6.7. Desiccant containing a color indicator of moisture concentration or an instrumental indicator

6.8. Drying ovens set at 103 -105 °C and 180 ± 2 °C. Separate ovens should be maintained at appropriate temperatures.

Note: Environmental Express StableWeigh TDS HotBlocks (Model # TDS024) are used for the initial drying at 103-105°C of the TDS bags. Bags are then transferred to a 180 ± 2°C oven to complete drying.

6.9. Muffle furnace (550 °C ± 50 °C)

6.10. Thermometers, NIST traceable

6.11. Conductivity meter and associated apparatus

6.12. Graduated cylinders, to deliver (TD), assorted sizes, Class A

6.13. Crucible tongs

6.14. Zetex gloves or other gloves capable of providing protection at 550 °C.

7. REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard.

7.1. Reagent water - Deionized water, with conductance <1 umhos/cm – to be used for blanks and rinsing

7.2. The LCS standard solution is commercially purchased. The true value varies from lot to lot when received from the manufacturer and the calculation is adjusted accordingly by the laboratory. The standard is received with a certificate of analysis with the true value listed on it and is retained by the laboratory. Follow manufacturer's instructions for storage and expiration date.

7.2.1. If the solution needs to be made by the laboratory the procedure is as follows: LCS solution (500 mg/L TSS and TDS, 1000 mg/L TS): Place 500.0 mg of diatomaceous earth (infusorial earth or celite 545) and 500 mg sodium chloride into a 1000 mL volumetric flask and dilute to volume with deionized water. Mix well. Store at room temperature. Prepare fresh every three months.

8. SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1. Samples should be collected in either plastic or glass bottles.

8.2. Samples must be stored at >0.0℃ but ≤6.0℃ to minimize microbiological decomposition of solids. Bring samples to room temperature before analysis.

8.3. To achieve the reporting limits listed in Section 1, the recommended minimum volume for samples is 100mL. If less than minimum volumes are used because of limited sample or solids loading this should be documented using an NCM to be included in the report case narrative.

8.3.1. Smaller samples sizes may be used for samples that are high in solids. Historical data, visual inspection and conductivity readings may be used to choose a different sample size for initial analysis.

8.4. Holding times for TDS and VDS determination is 7 days from the date of sampling to begin the analysis.

9. QUALITY CONTROL

9.1. Method Blank (MB): One method blank must be processed with each batch of 20 or fewer samples. The method blank consists of reagent water that is carried through the entire analytical procedure, including filtration as applicable. The method blank is used to identify any system and process interferences or contamination of the analytical system that may lead to the reporting of elevated analyte concentrations or false positive data.

9.1.1. Use 100mL of reagent water for MB analysis.

9.1.2. Corrective Action for Blank Contamination:

If the analyte level in the method blank is $\geq$ the RL for the analyte of interest in the sample, all associated samples with reportable levels of analyte must be reanalyzed, unless the sample concentrations are >10x the blank concentration. If reanalysis is not possible due to limited sample quantity or holding time considerations, the project manager must be notified so that the client can be informed. Results reported associated with a contaminated method blank (unless sample >10X blank) must be reported with a B qualifier and the failure narrated through the appropriate NCM:

- For samples that have results <RL, use “Method Blank – Report, ND”
- For samples that have results >RL and <10x MB, use “Method Blank - >1/2RL” and correct the associated narrative to state “greater than the reporting limit”.
- For samples that have results >10x MB concentration, use “Method Blank – Report, 10X”

9.1.3. High blank results indicate contamination. Make sure the glassware and filtering apparatus is clean before repeating the analysis.

9.1.4. If MB results are negative (dish weighs less after analysis), this indicates that the balance was not operating correctly or the filter/weighing dish was not completely dry when the initial weights were measured. If MB results are below the negative RL (a change of -0.0010g for example), all samples with concentrations <10X the RL should be reanalyzed if possible. If reanalysis is not possible, the negative blanks and possible negative bias for the sample results must be narrated using the "Other – Deficiency" NCM.

9.2. Laboratory Control Sample (LCS): One LCS must be processed with each batch of 20 or fewer samples. The LCS must be carried through the entire analytical procedure. The LCS is used to monitor the accuracy of the analytical process. On-going monitoring of the LCS results provides evidence that the laboratory is performing the method within acceptable accuracy and precision guidelines.

9.2.1. No LCS is available for the volatile residue procedure.

9.2.2. Refer to Section 7.2 for instructions on how to prepare the LCS solution, unless using a purchased standard. The LCS analysis volume must be calculated to produce a final residue between 2.5 and 200mg.

9.2.3. The LCS percent recovery must be within 80 -120% of the true or certified value.

9.2.4. If LCS recovery is outside the control limits, all associated samples must be reanalyzed with an acceptable LCS, unless the original LCS recovery is high and samples results are <RL.

9.2.4.1. If reanalysis is not possible due to limited sample quantity or holding time considerations, the project manager must be notified so that the client can be informed. Results reported associated with a failed LCS must be reported with the appropriate result qualifier and the failure narrated through the appropriate NCM:

- For high LCS recovery and associated samples <RL, use "LCS/LCSD - %R High".
- If samples are reanalyzed due to failed LCS, and the reanalysis occurs past the holding time, use "LCS/LCSD - %R, RX/RA Batch, Outside".
- If there is insufficient sample volume to perform a reanalysis, use "LCS/LCSD – Insufficient Sample".

9.2.5. Poor LCS results are usually the result of contamination or poor mixing. Make sure to shake the LCS and all samples very well before pouring out the portion to be filtered or analyzed. Do not allow the sample to settle in the graduated cylinder.

9.3. Duplicate (D): A duplicate sample analysis is required with every 10 samples or less for all methods.

9.3.1. Sample and Duplicate results must agree within 10% RPD.

9.3.2. The failure of the sample duplicates to meet precision criteria must be addressed in the case narrative.

9.3.3. Make sure to shake all samples very well before pouring out the portion to be filtered or analyzed to improve homogenization and precision. Do not allow the sample to settle in the graduated cylinder before analyzing.

9.3.4. On-going method precision is documented using LCS control charting.

10. PROCEDURE

10.1. Calibration and Standardization

10.1.1. Proper balance operation will be verified daily or prior to sample analysis by following the balance calibration SOP, PT-QA-12. Analytical balance calibration must be verified at least every 24 hours, and prior to using the balance each day. Weights used for calibration verification, prior to initial and read-back weighings, are documented in the TALS batch information.

10.1.1.1. For TDS and VDS, balances are verified using 2mg, 0.300g, 10g and 120g weights.

10.1.1.2. Balance reading for the 2mg weight must be 0.0018g - 0.0022g; for the 0.300 g weight must be 0.2995g – 0.3005 g; for the 10g weight must be 9.9900g – 10.0100g and for the 120g weight must be 119.88000g – 120.1200g. If any reading falls outside these limits, the balance must be recalibrated and the verification performed again with all weights in the group..

10.1.2. Oven temperature must be checked daily and recorded in the oven temperature logbook. Oven temperatures must be kept between 103-105^{o}C and 178-182^{o}C. The temperature of the Muffle furnace used for volatile residues analyses is documented at the time of use.

10.1.3. Conductivity of the water must be monitored and recorded in the Conductivity Logbook daily. The maximum permissible conductivity is 1.0 umhos/cm (at 25 °C). If the conductivity reading on the water system exceeds this level, do not use the water for these procedures and notify the supervisor immediately.

10.2. Procedure

10.2.1. All samples are to be electronically checked out of sample control with the TALS internal chain of custody (ICOC) program.

10.2.2. Proper sample identification is extremely important in any analytical procedure. Labeling of evaporating dishes and filters holders must be done in a manner to ensure connection with the proper sample. Labeling must be done in a way that will not be compromised by the heat used.

10.2.3. If samples are visibly oily, this should be noted on the TALS Worksheet Notes or Batch Information Comments.

10.2.4. If there is limited sample volume or high solids content, smaller amounts of sample may need to be processed than detailed in the following sections. This occurrence must be noted on the TALS Worksheet. Reporting limits are adjusted according to the actual sample volume used.

10.2.5. All weights are recorded to the nearest 0.1mg directly from the balance into the TALS Worksheet using balance upload. If the balance upload is not working, the weights are recorded in the Wet Chemistry Raw Data Logsheet for transfer to the TALS Worksheet. If the manual Logsheet is used, it must be scanned to a pdf and attached to the TALS batch as raw data.

10.2.6. Prepare TALS analytical batches prior to beginning analysis, as the batch must be available to upload initial weights and record sample volumes used.

10.2.7. The conductance of each sample is checked prior to sample filtration, to be used to determine the appropriate sample volume to process.

10.2.7.1. Allow the sample to warm to near room temperature before checking conductivity. Shake the sample well, rinse the conductivity cell with two portions of the sample, and then allow the conductivity reading of a third portion to settle. Record the conductivity on the TALS Worksheet (see Figure 2). Rinse the conductivity cell with laboratory reagent water between samples.

10.2.7.2. TDS is typically 55 - 90% of the conductance result. The exact relationship depends on the compounds present in the samples and may not hold for very high concentrations or samples containing non-ionic species or samples with conductance greater than 10,000 µmho/cm or less than 50 µmho/cm.

- If the sample has a conductance less than 2500 µmhos/cm, 100 mL should be used.

- If the sample has a conductance over 3,000 µmhos/cm, to achieve a residue of <200mg, the following formula should be used to approximate the required sample volume:

  (2000 x 100) / Conductivity = mL sample to use

  Note: To avoid odd reporting limits, and make measuring easier, round the determined sample volume to one of the following volume increments: 5, 10, 20, 25, 50, or 100 mL.

10.3. Total Dissolved Solids – SM 2540C

10.3.1. Preparation of Glass Fiber Filter Disc, if not purchased prepared for use:

- Place the glass fiber filter discs, one at a time, on the membrane filter apparatus with wrinkled surface side up.
- While vacuum is applied, wash the disc with three successive 20 mL volumes of reagent water.
- Remove all traces of water by continuing to apply vacuum after water has passed through and discard washings.
- If TSS analysis is to be performed along with the TDS, follow the additional filter drying steps in SOP PT-WC-043.

10.3.2. Preparation of Evaporating Dishes: (Evaporating dishes must be used if VDS is to be determined.)

10.3.2.1. If only total dissolved solids are to be measured, heat a clean evaporating dish or glass beaker to 180 ± 2 °C for one hour. If volatile dissolved solids are to be measured in addition to TDS, ignite the clean evaporating dish at 550 ± 50 °C for one hour in a muffle furnace.

10.3.2.2. Heat resistant gloves and tongs must be used when removing items from the muffle furnace.

10.3.2.3. Store and cool dish in desiccator until dish reaches room temperature or until needed.

10.3.2.4. Weigh immediately before use to the nearest 0.1 mg. Upload weight into the TALS Worksheet for the associated sample (see Figure 2).

10.3.3. If Environmental Express StableWeigh bags are used, the bags require no pre-drying or weighing. Scan the barcode on the bag to enter the bag weight into the TALS worksheet.

10.3.4. Sample Analysis:

10.3.4.1. Thoroughly rinse the entire filtration apparatus with reagent water before filtering each sample. Remove as much of the rinse water as possible from the filtration flask.

10.3.4.2. Assemble the filtering apparatus. Place a glass fiber filter on the funnel base, wrinkled surface side up. Attach the funnel cup. Pre-wet the filter using a few mL of reagent water and begin suction.

Note: If the sample also requires TSS, follow the analytical steps in SOP PT-WC-043 for recording the initial filter weights.

10.3.4.3. Shake the sample vigorously and rapidly transfer 100 mL, or a smaller portion which will yield between 10 and 200 mg dried residue, to the funnel by means of a graduated cylinder. (Pre-determine the volume to use following step 10.2.8 above.)

- If total dissolved solids content is low, <2.5mg of residue is obtained from the initial analysis, successive sample volumes may be filtered and added to the original dish.

- If more than 10 minutes are required to complete filtration, decrease sample size.

10.3.4.4. Record the volume of sample used (to the nearest mL) on the benchsheet.

10.3.4.5. For the method blank, process 100 mL of reagent water as the sample.

10.3.4.6. For the LCS, process 50 mL of the LCS Solution and dilute to a final volume of 100 mL with Reagent water. Refer to Section 7.2 for instructions on how to prepare the LCS if not using a purchased standard.

10.3.4.7. Filter the sample through the glass fiber filter.

10.3.4.8. Rinse the graduated cylinder, funnel walls, and filter with three successive 10 mL portions of reagent water and allow for complete drainage between washings. Continue to apply vacuum for about three minutes after filtration is complete to remove as much water as possible.

10.3.4.9. Transfer the filtrate (including the washings) to a pre-weighed evaporating dish. Rinse the receiving flask with 10 - 25 mL of reagent water and transfer washings into the dish to ensure complete transfer of the sample.

Note: If TSS analysis is being performed along with the TDS, refer to SOP PT-WC-043 for steps to take with the filter for this analysis.

Note: If StableWeigh bags are used, the sample has been filtered directly into the drying vessel (bag). (See Figure 5 at the end of this document.) Remove the bag from the filtering apparatus and transfer it to the rack.

10.3.4.10. Place the dishes into the 103-105°C oven overnight to evaporate the water.

Note: If StableWeigh bags are being used, transfer the racks to the StableWeigh HotBlocks. HotBlocks are maintained at 103-105°C. Bags are heated to dryness in the block, or may be left in the block overnight.

10.3.4.11. Transfer the evaporated sample containers (dishes or bags) into the 180 ± 2°C oven, and bake for at least one hour after the temperature returns to 180 ± 2°C.

10.3.4.12. Record the dates, times, and oven temperatures for in and out of the ovens or block on the TALS Batch Information (see Figure 9).

10.3.4.13. Using tongs, remove the weighing vessel from the oven and place in a desiccator and cool to room temperature.

10.3.4.14. Weigh the vessel to the nearest 0.1 mg. This weight is automatically uploaded into the TALS Worksheet using the Balance Link program (see Figure 2).

10.3.4.15. If the residue is >0.2g, start the analysis over again with a smaller sample volume. If insufficient volume is available for reanalysis, proceed with the steps below, and narrate that the results were determined from a residue >200mg.

10.3.4.16. Return the samples to the oven for at least another hour, cool in a desiccator, and reweigh. Repeat the drying, cooling, desiccating, and weighing cycle until a constant weight is obtained. Constant weight is considered a weight change < 0.5 mg or < 4% of the previous weight, whichever is less. If more than three cycles are required, use the third cycle weights and initiate a Nonconformance Memo.

Note: When weighing dried sample, be alert to change in weight due to air exposure and/or sample degradation. Note any change in sample residue appearance in the TALS Worksheet Notes.

10.3.4.17. TALS will automatically calculate the sample result from the data entered into the Worksheet. Check the calculations according to the equation in Section 11.1. Use the lowest final weight achieved for calculating TDS.

10.4. Volatile Dissolved Solids – SM2540E

10.4.1. Heat muffle furnace up to temperature (550 ± 50 °C).

10.4.2. Place evaporating dish containing residue generated by Total Dissolved Solids protocol (Section 10.3.3.17) in muffle furnace to ignite the residue.

10.4.3. Record the date, time, and muffle furnace temperature in the TALS Batch Information when the samples are initially placed in the oven and again when they are removed from the oven (see Figure 3).

10.4.4. Heat samples for at least 15 minutes. Typically 15-20 minutes ignition is sufficient for 200 mg of residue. However, more than one sample and/or heavier residues may necessitate longer ignition times.

10.4.5. Using tongs and heat resistant gloves, remove the weighing dish from the muffle furnace and place in a desiccator and cool to room temperature. Weigh dish when it has cooled to room temperature, and upload the weight into the TALS Worksheet (see Figure 4).

10.4.6. Return the samples to the furnace for another 15 minutes, cool in a desiccator and reweigh. Repeat the drying, cooling, desiccating and weighing cycle until a constant weight is obtained. Constant weight is considered a weight change of < 0.5mg or < 4% of the previous weight, whichever is less. If constant weight has not been achieved after 3 cycles of heating, cooling and weighing; document the 3 weights and do not perform any further cycles. Document that only 3 heating cycles were performed, and the lowest weight of the 3 is used for reporting in an NCM.

10.4.7. TALS will calculate the final results. Check calculations using the formula given in Section 11.2. Use the lowest final weight achieved for calculating VDS.

11. CALCULATIONS / DATA REDUCTION

11.1. Calculate Total Dissolved Solids as follows:

$$\text{Total Dissolved Solids, mg / L} = \frac{(A - B) \times 1000}{C}$$

Where: A = weight of dried residue + dish (mg)
B = weight of dish (mg)
C = volume of sample (mL)

11.2. Calculate Volatile Dissolved Solids as follows:

$$\text{Volatile Dissolved Solids, mg / L} = \frac{(A - B) \times 1000}{C}$$

Where: A = weight of residue + dish before ignition (mg)
B = weight of residue + dish after ignition (mg)
C = volume of sample (mL)

11.3. The relative percent difference (RPD) of duplicates are calculated according to the following equation:

$$RPD = 100\left[\frac{|DU1 - DU2|}{\left(\frac{DU1 + DU2}{2}\right)}\right]$$

Where: DU1 = Sample result
DU2 = Sample duplicate result

11.4. LCS Percent Recovery

$$\text{LCS Percent Recovery} = \left(\frac{\text{Observed Conc. in LCS}}{\text{True LCS Conc.}}\right) \text{x } 100 \text{ Percent}$$

11.5. If multiple weighing cycles are required, the lowest final sample weight is used for calculating solids content.

11.6. If smaller or larger sample volumes are processed than are specified in the method, the reporting limit must be adjusted accordingly.

11.7. Sample results should be reported according to the following significant figure rules:

Significant Figures	Sample Result
2	< 10
3	≥ 10

12. METHOD PERFORMANCE

12.1. The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual for additional information concerning Precision and Accuracy.

12.2. Demonstration of Capabilities – Prior to the analysis of samples, a Demonstration of Capabilities (DOC) as described in the QA Manual, must be performed initially, annually and any time a significant change is made to the analytical system.

12.3. An MDL standard study is not performed for this procedure. The reporting limit is verified annually by Method Blank MDL calculation. Results are not reported below the RL.

13. POLLUTION CONTROL

13.1. It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2. This method does not contain any specific modifications that serve to minimize or prevent pollution

14. WASTE MANAGEMENT

14.1. Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001.

14.2. The following waste streams are produced when this method is carried out.

14.2.1. Unpreserved, non-hazardous samples are disposed down a lab sink.

14.2.2. Oily waste samples are disposed of into waste stream #10 – flammable sample waste.

1. SCOPE AND APPLICATION

1.1 This SOP describes the application of the Toxicity Characteristic Leaching Procedure (TCLP), SW846 Method 1311. The Toxicity Characteristic (TC) of a waste material is established by determining the levels of 8 metals and 31 organic chemicals in the aqueous leachate of a waste. The TC is one of four criteria in 40 CFR Part 261 to determine whether a solid waste is classified as a hazardous waste. The TC Rule utilizes the TCLP method to generate the leachate under controlled conditions that are designed to simulate leaching through a landfill. EPA's "worst case" waste disposal model assumes mismanaged wastes will be exposed to leaching by the acidic fluids generated in municipal landfills. The EPA's model also assumes the acid/base characteristics of the waste will be dominated by the landfill fluids. The TCLP procedure directs the testing laboratory to use a more acidic leaching fluid if the sample is an alkaline waste, again in keeping with the model's assumption that the acid fluids will dominate leaching chemistry over time.

1.2 A specific list of TC analytes and regulatory limits may be found in Appendix A, Table 3.

1.2.1 **Note:** The list in Appendix A does not include the December 1994 EPA rule for Universal Treatment Standards for Land Disposal Restrictions. Those requirements include 216 specific metallic and organic compounds and, in some cases, lower detection limit requirements (see 40 CFR 268.40). TCLP leachates are part of the new Universal Treatment Standards, but the conventional analytical methods will not necessarily meet the new regulatory limits. Consult with the client and with TestAmerica Technical Specialists before establishing the instrumental methods for these regulations.

1.3 This SOP also describes the application of the Synthetic Precipitation Leaching Procedure (SPLP) that was designed to simulate the leaching that would occur if a waste was disposed in a landfill and exposed only to percolating rain water. The procedure is based on SW846 Method 1312. The list of analytes for SPLP may extend beyond the toxicity characteristic compounds shown in Appendix A. With the exception of the use of a modified extraction fluid, the SPLP and TCLP protocols are essentially equivalent. Where slight differences may exist between the SPLP and TCLP they are distinguished within this SOP.

1.4 The procedure is applicable to liquid, solid, wastes and multiphasic wastes.

1.5 The results obtained are highly dependent on the pH of the extracting solution, the length of time that the sample is exposed to the extracting solution, the temperature during extraction, and the particle size/surface area of the sample. These parameters must be carefully controlled. Any deviations from the method affecting these parameters must be documented as a nonconformance, with a cause and corrective action described.

1.6 The reporting limits are based on the individual samples as well as the individual analysis techniques. However, the sample is determined to be hazardous if it contains any analyte at levels greater than or equal to the regulatory limits.

1.7 If a total analysis of the waste demonstrates that individual analytes are not present in the waste, or that they are present but at such low concentrations that the appropriate regulatory levels could not possibly be exceeded, the TCLP procedure need not be run. If the total analysis results indicate that TCLP is not required, the decision to cease TCLP analysis should be remanded to the client.

1.8 If an analysis of any one of the liquid fractions of the procedure leachate indicates that a regulated compound is present at such a high concentration that, even after accounting for dilution from the other fractions of the leachate, the concentration would be equal to or above the regulatory level for that compound, then the waste is hazardous and it may not be necessary to analyze the remaining fractions of the leachate. However, the remaining analyses should not be terminated without the approval of the client.

1.9 Volatile organic analysis of the leachate obtained using a bottle extraction, normally used for extractable organics and metals, can be used to demonstrate that a waste is hazardous, but only the ZHE option can be used to demonstrate that the concentration of volatile organic compounds is below regulatory limits.

1.10 On occasion clients may request modifications to this SOP. These modifications are handled as indicated in PT-QA-M-001, Quality Assurance Manual.

1.11 One-time procedural variations are allowed only if deemed necessary in the professional judgment of management to accommodate variation in sample matrix, radioactivity, chemistry, sample size, or other parameters. Any variation in procedure shall be completely documented on a Nonconformance Memo kept in the project file and described in the final report. The variation must be approved by the Project Manager and Technical Director or QA Manager. Any unauthorized deviations from this procedure must also be documented as a nonconformance, with a cause and corrective action described.
NOTE: TCLP is a “method defined parameter” as such any changes from the method may invalidate the analytical results. Careful consideration by the technical staff and discussion with the QA department is required before any procedural changes occur.

1.12 For subsampling procedures refer to SOP PT-QA-024.

2. SUMMARY OF METHOD

2.1 For liquid wastes that contain less than 0.5% dry solid material, the waste, after filtration through 0.6 to 0.8 µm glass fiber filter, is defined as the TCLP or SPLP leachate.

2.2 For wastes containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solids and stored for later analysis. The particle size of the remaining solid phase is reduced, if necessary. The solid phase is extracted with an

amount of extraction fluid equal to 20 times the weight of the solid phase. For TCLP, the extraction fluid employed for extraction of non-volatile analytes is a function of the alkalinity of the solid phase of the waste. For SPLP, the extraction fluid employed is a function of the region of the country where the sample site is located if the sample is a soil. Two leachates may be generated: a) one for analysis of non-volatile constituents (semi-volatile organics, pesticides, herbicides and metals and/or b) one from a Zero Headspace Extractor (ZHE) for analysis of volatile organic constituents. Following extraction, the liquid leachate is separated from the solid phase by filtration through a 0.6 to 0.8 µm fiber filter.

2.3 If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid leachate and these are prepared and analyzed together. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

3. DEFINITIONS

3.1 Leachate - the TCLP or SPLP extract (aqueous solution) generated from this procedure.

3.2 Percent Wet Solids - that fraction of a waste sample (as a percentage of the total sample) from which no liquid may be forced out by an applied pressure.

3.3 TALS – TestAmerica Laboratory Information Management System

3.4 NCM - Non-Conformance Memo – a system within TALS for the lab to communicate to project management and others when there is an anomaly seen with the samples or batch, or a QC failure.

3.5 Refer to the glossary in the Quality Assurance Manual PT-QA-M-001 for additional definitions.

4 INTERFERENCES

4.5 Oily wastes may present unusual filtration and drying problems. As recommended by EPA (see Figure 3), oily wastes will be evaluated on an individual basis. This applies specifically to samples containing viscous non-aqueous liquids that would be difficult to filter.

4.6 Wastes containing free organic liquids (i.e., those with separable non-aqueous liquid phases) will be assumed to be 100% liquid and totals analysis will be performed to determine if the oil exceeds TCLP limits.

4.7 Solvents, reagents, glassware and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be

demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks as described in the Section 9.0 and the individual determinative SOPs.

4.8 Glassware and equipment contamination may result in analyte degradation. Soap residue on glassware and equipment may contribute to this. All glassware and equipment should be rinsed very carefully to avoid contamination.

4.9 Phthalates may be eliminated by proper glassware cleanup and by avoiding plastics. Only glass, Teflon, or Type 316 stainless steel tumblers may be used for leachates to be analyzed for organics. Plastic tumblers may be used for leachates to be analyzed for metals only.

4.10 Overexposure of the sample to the environment will result in the loss of volatile components.

4.11 Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

5 SAFETY

5.1 Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001), the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.2 The following is a list of the materials used in this method, which have a serious or significant hazard rating. This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table. A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

Material (1)	Hazards	Exposure Limit (2)	Signs and symptoms of exposure
Acetic Acid	Corrosive Poison Flammable	10 ppm-TWA	Contact with concentrated solution may cause serious damage to the skin and eyes. Inhalation of concentrated vapors may cause serious damage to the lining of the nose, throat, and lungs. Breathing difficulties may occur.
Hydrochloric Acid	Corrosive Poison	5 ppm-Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failure, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Nitric Acid	Corrosive Oxidizer Poison	2 ppm-TWA 4 ppm-STEL	Nitric acid is extremely hazardous; it is corrosive, reactive, an oxidizer, and a poison. Inhalation of vapors can cause breathing difficulties and lead to pneumonia and pulmonary edema, which may be fatal. Other symptoms may include coughing, choking, and irritation of the nose, throat, and respiratory tract. Can cause redness, pain, and severe skin burns. Concentrated solutions cause deep ulcers and stain skin a yellow or yellow-brown color. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Sodium Hydroxide	Corrosive	2 Mg/M3-Ceiling	Severe irritant. Effects from inhalation of dust or mist vary from mild irritation to serious damage of the upper respiratory tract, depending on severity of exposure. Symptoms may include sneezing, sore throat or runny nose. Contact with skin can cause irritation or severe burns and scarring with greater exposures. Causes irritation of eyes, and with greater exposures it can cause burns that may result in permanent impairment of vision, even blindness.
1 – Always add acid to water to prevent violent reactions.			
2 – Exposure limit refers to the OSHA regulatory exposure limit.			

5.3 Eye protection that protects against splash, laboratory coat, and appropriate gloves must be worn while samples, standards, solvents, and reagents are being handled. Cut resistant gloves must be worn doing any other task that presents a strong possibility of getting cut. Disposable gloves that have become contaminated will be removed and discarded, other gloves will be cleaned immediately.

5.4 Gas pressurized equipment is employed in this procedure. Be sure all valves and gauges are operating properly and that none of the equipment, especially tubing, is over-pressurized. **CAUTION:** Do not open equipment that has been pressurized until it has returned to ambient pressure.

5.5 A rotary agitation apparatus is used in this procedure. Certain samples may break the glass jars used in the procedure. For these samples, extra caution, including plastic or polyethylene overwraps of the glass jar, may be necessary.

5.6 Secure the tumbler and extraction apparatus before starting rotary agitation apparatus. Once the tumbler apparatus is started the area around the apparatus is roped off to prevent injury.

5.7 During sample rotation, pressure may build up inside the bottle. Periodic venting of the bottle will relieve pressure.

5.8 Exposure to chemicals must be maintained as low as reasonably achievable, therefore, unless they are known to be non-hazardous, all samples must be opened, transferred and prepared in a fume hood, or under other means of mechanical ventilation. Solvent and waste containers will be kept closed unless transfers are being made.

5.9 The preparation of standards and reagents and glassware cleaning procedures that involve solvents such as methylene chloride will be conducted in a fume hood, outside of the TCLP room, with the sash closed as far as the operation will permit.

5.10 All work must be stopped in the event of a known or potential compromise to the health and safety of a TestAmerica associate. The situation must be reported **immediately** to a laboratory supervisor or EH&S coordinator.

5.11 Due to the potential for ignition and/or flammability, do not attempt to dry non-aqueous liquid samples in an oven.

6 EQUIPMENT AND SUPPLIES

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirements in this SOP can be met.

6.1 Extraction vessels

6.1.1 For volatile analytes - zero-headspace extraction (ZHE) vessel, gas-pressure actuated, Millipore YT3009OHW or equivalent (see Figure 2 in Appendix B).

6.1.1 For metals - either borosilicate glass jars (2.5 L plastic-coated, with Teflon lid inserts) or 2 L HDPE (Nalgene or equivalent) bottles may be used.

6.1.2 For non-volatile organics - only borosilicate glass may be used.

6.2 Vacuum filtration apparatus, capable of 0 - 50 psi and stainless steel pressure filtration apparatus (142 mm diameter), capable of 0 - 50 psi.

6.3 Borosilicate glass fiber filters, 0.6 - 0.8 µm (Whatman GF/F 14.2 cm, 0.7 µm or equivalent). When analyzing for metals, wash the filters with 1 N nitric acid and de-ionized water prior to use. As an alternative, certified pre-washed filters may be used. Glass fiber filters are fragile and should be handled with care.

6.4 Rotary agitation apparatus, multiple-vessel - Associated Design and Manufacturing Company 3740-6 or equivalent (see Figure 1). The apparatus must be capable of rotating the extraction vessel in an end-over-end fashion at 30 ± 2 rpm.

6.5 ZHE Extract Collection Devices are used to collect the initial liquid phase and the final extract of the waste from the ZHE device, either of the following may be used:

6.5.1 Gas-tight syringes, 100 mL capacity, Hamilton 0158330 or equivalent,

6.5.2 or dispense leachate directly into a VOA vial.

6.6 Top loading balance, capable of 0 - 4000 ± 0.01g (all measurements are to be within ± 0.1 grams).

6.7 pH meter and probe capable of reading to the nearest 0.01 unit, and with automatic temperature compensation. (Accumet XL150 pH meter or equivalent)

6.8 Magnetic stirrer/hotplate and stirring bars

6.9 VOA vials, 40 mL, with caps and septa

6.10 Glass jars, 1/2 - 1 gallon, with Teflon lid-liners

6.11 Nalgene plastic bottles, 1 liter

6.12 Peristaltic pump, Cole Parmer or equivalent

6.13 Miscellaneous laboratory glassware and equipment

7 REAGENTS AND STANDARDS

The following items are recommended for performing this procedure. Equivalent items should only be used when they result in an improvement in quality, efficiency, productivity, or cost. An item can be considered equivalent if with its use, the analytical and QA/QC requirement in this SOP can be met. Please refer to the SDS prior to the use of any reagent or standard.

Reagent grade, or better, chemicals must be used unless otherwise indicated. Follow manufacturer's instructions for storage and expiration.

7.1 Reagent water for non-volatile constituents must be produced by a Millipore DI system or equivalent. For volatile constituents, water must be passed through an activated carbon filter bed (Milli-Q or tap water passed through activated carbon). Reagent water must be free of the analytes of interest as demonstrated through the analysis of method blanks.

7.2 Hydrochloric acid, 1 N: Carefully add 83.3 mL concentrated HCl to 800 mL reagent water, cool and dilute to 1 liter with reagent water. Cap and shake to mix well. Store at room temperature. This solution expires 1 year after preparation.

CAUTION: Always add acid to water to avoid splattering.

7.3 Nitric acid, concentrated, (HNO_3)

7.4 Sodium hydroxide, 1 N, purchased or prepared: Carefully add 40 g reagent grade NaOH pellets to 800 mL reagent water, stir until the pellets are completely dissolved, cool and dilute to 1 liter with reagent water. Store at room temperature. If prepared in the laboratory, this solution expires 1 year after preparation.

CAUTION: Significant heat is generated in the preparation of this reagent.

7.5 Acetic acid, glacial: concentrated, reagent grade liquid (HOAc).

7.6 pH calibration solutions: pH Buffers of 2, 4, 7, 10 and 13 - Purchased with certificate of analysis. A fresh portion of buffer solution must be used each day of analysis.

7.7 **TCLP Leaching Fluids**

7.7.1 The pH of both solutions listed below must be checked and recorded daily with use. The pH meter/probe must be calibrated prior to daily use.

7.7.2 TCLP Leaching Fluid 1 is purchased from Ricca Chemical Company, TCLP Leaching Fluid 2 is purchased from Lab Chem. Fluids may be prepared following the procedure outlined in sections 7.7.5 and 7.7.6. If prepared in the

laboratory, the solution expires 1 year after preparation, or if the pH falls outside the required range.

7.7.3 The leaching fluids MUST be prepared correctly. If the desired pH range is not achieved and maintained, the TCLP may yield erroneous results due to improper leaching. If the pH is not within the specifications, the fluid must be discarded and fresh extraction fluid prepared. The pH of purchased and prepared TCLP fluids must be checked prior to each day's use, and the actual pH is recorded in the TALS batch.

7.7.4 Additional volumes of extraction fluids listed above may be prepared by multiplying the amounts of acetic acid and NaOH by the number of liters of extraction fluid required.

7.7.5 TCLP Fluid #1: Carefully add 5.7 mL glacial acetic acid and 64.3 mL of 1 N NaOH to 500 mL reagent water in a 1 liter volumetric flask. Dilute to a final volume of 1 L with reagent water, cap and shake to mix well. When correctly prepared, the pH of this solution is 4.93 ± 0.05.

7.7.6 TCLP Fluid #2: Carefully add 5.7 mL glacial acetic acid to 500 mL reagent water in a 1 liter volumetric flask. Dilute to a final volume of 1 L with reagent water, cap and shake to mix well. When correctly prepared, the pH of this solution is 2.88 ± 0.05.

7.8 Nitric acid, 20% solution: Slowly and carefully add 200 mL concentrated HNO_3 to 800 mL reagent water. Cap and shake to mix well. Store at room temperature. This solution expires 1 year after preparation.

7.9 Sulfuric acid / nitric acid - 60/40 weight percent mixture. Cautiously mix 60 g of concentrated sulfuric acid with 40 g of concentrated nitric acid. Store at room temperature. This solution expires 1 year after preparation.

7.10 SPLP Leaching fluids

7.10.1 SPLP Leaching Fluids are purchased from Lab Chem Inc. or prepared following the procedures outlined below. The pH of SPLP fluids must be checked prior to each day's use. If not within specifications, the fluid is discarded and fresh fluid prepared.

7.10.2 SPLP fluid #1: Add 60/40 weight percent mixture of sulfuric and nitric acids (7.9) to reagent water until the pH is 4.20 ± 0.05. This fluid is used for soils from a site that is east of the Mississippi River and for wastes and wastewaters.

7.10.3 SPLP fluid #2: Fluid #1 is diluted with laboratory reagent water until the pH is 5.00 ± 0.05. This fluid is used for soils from a site that is west of the Mississippi River.

7.10.4 DI Water for SPLP Volatiles leaching - This is laboratory reagent water. SPLP leaching for Volatiles and always performed with DI water only. Additionally, any cyanide-containing waste or soil is leached with DI water because leaching of cyanide containing samples under acidic conditions may result in the formation of hydrogen cyanide gas.

7.11 Methanol - used to aid in cleaning oil-contaminated equipment

7.12 Metals Spiking Standards – See Table 4 at the end of this document for details

7.13 Nitric Acid, concentrated – used for preserving leachates' MS/MSD volume for metals analysis. Sample aliquots for metals are filtered directly into pre-preserved bottles containing nitric acid.

8 SAMPLE COLLECTION, PRESERVATION, SHIPMENT AND STORAGE

8.1 Samples being analyzed for non-volatile organic compounds should be collected and stored in glass containers with Teflon lid liners.

8.2 Samples being analyzed for metals only can be collected in either glass or polyethylene containers.

8.3 When the waste is to be evaluated for volatile analytes, care should be taken to minimize the loss of volatiles. Samples shall be collected and stored in a manner intended to prevent the loss of volatile analytes (e.g., samples should be collected in Teflon lined septum capped vials with minimal headspace and stored at >0.0 °C but ≤6.0°C).

8.3.1 Samples should not be cooled for shipment or storage <u>if doing so will change the composition of the sample</u>.

8.3.2 Samples should be opened only immediately prior to extraction.

8.4 Samples must not have any chemical preservation prior to leaching. Chemical preservatives are never added to leachates generated for organic analysis. Chemical preservation is added only to inorganic parameters after leaching and filtration.

8.5 Samples should be refrigerated to >0.0 °C but ≤6.0°C, unless refrigeration results in irreversible physical changes to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

8.6 The minimum TCLP or SPLP sample collection size is determined by the physical state or states of the waste and the analytes of concern. The amount of waste required varies with the percent solids. The lower the percent solids, the more waste will be required for preliminary and final testing. For aqueous samples containing between 0.5 and 10% solids, several kilograms of sample are required to complete the analyses. The general minimal requirements when the samples are 100% solids include: 1 - 32 oz jar for semi-volatile organic analysis and metals, and 1 - 4 oz jar for volatile organic analysis. Low-density sample materials, such as rags or vegetation, will require larger volumes of sample. For liquid samples (less than 50% solids), minimum requirements are 2 - 32 oz jars for semi-volatile organic analysis and metals, and 2 - 8 oz jars for volatile organic analysis. If volatile organic analysis is the only requested parameter, 2 separate jars are required. If matrix spike or duplicate control samples are requested, additional sample volume is required. If sufficient sample volumes were not received, analyses cannot be started and the client should be notified as soon as possible. Reduced volume will only be done if there is insufficient sample received from the client.

8.7 TCLP or SPLP leachates should be prepared for analysis and analyzed as soon as possible following extraction. Leachates or portions of leachates for metallic analyte determinations must be acidified with nitric acid to a pH less than 2, unless precipitation occurs. If precipitation occurs upon addition of nitric acid to a small aliquot of the leachate, then the remaining portion of the leachate shall not be acidified and the leachate shall be analyzed as soon as possible. All other leachates should be stored under refrigeration (>0.0 °C but ≤6.0°C) until analyzed. ZHE leachates must be stored in VOA vials filled to eliminate all headspace.

8.8 Samples are subject to appropriate treatment within the following time periods:

Table 1 – Holding Times

Parameter	Collection to Start of TCLP/SPLP Leach	End of TCLP/SPLP Tumble to Semi-Volatile Extraction	End of TCLP/SPLP Leach or Semi-volatile Extraction to Analysis
Volatiles	14	N/A	14
Semivolatiles	14	7	40
Mercury	28	N/A	28
Other Metals	180	N/A	180

NOTE: The initial holding time is measured from date of collection to date TCLP/SPLP extraction started. (This should be the TCLP/SPLP extraction date in TALS LIMS.) Semi-volatile method prep holding time is measured from the day tumbling is complete to the start of method extraction. Subsequent analysis holding times are measured from the date extraction (TCLP/SPLP or method prep) starts**.** If sample holding times are exceeded, the values obtained will be considered minimal concentrations. Exceeding holding times is not acceptable in establishing that a waste does not exceed the regulatory level. Exceeding the holding time will not invalidate characterization if the waste exceeds the regulatory limit. The Total Elapsed Time is to be used as guidance. If preps are initiated at the last possible moment of a holding time, the elapsed times may be exceeded.

9. QUALITY CONTROL

9.1 A Quality Control Batch (QC Batch) is a set of up to 20 field samples of similar matrix that behave similarly and are processed using the same procedures, reagents and standards within the same time period. The same lot of reagents must be used within a batch. A minimum of one TCLP/SPLP extraction blank (Method Blank), and enough leachate to prepare one Matrix Spike (MS), and one Matrix Spike Duplicate (MSD) are required with each TCLP/SPLP leachate batch.

9.2 TCLP/SPLP Extraction Blanks - A minimum of one blank (using the same extraction fluid as used for the samples) must be prepared and analyzed for every batch of

samples extracted in a particular vessel type. The blanks are generated in the same way as the samples (i.e., blanks will be tumbled and filtered with the samples). Consult the individual analytical Method SOPs for blank acceptance criteria.

Note: ZHE vessels are uniquely numbered. Each time a new batch is set up the blank should be rotated sequentially to the next vessel to ensure all vessels are periodically checked. A blank is required to be performed at least every 20th time a vessel is used (see Appendix C for Example Blank Vessel Rotation Forms).

9.3 Matrix Spike (MS/MSD) - Matrix spikes are used to monitor the performance of the analytical methods on the matrix and to assess the presence of interferences. MS/MSD generation will be done when client requested with each batch of 20 samples.

9.3.1 Matrix spikes are added after filtration of the TCLP/SPLP leachate. Spikes are not added prior to the TCLP/SPLP leaching. For metals, matrix spikes are to be added before preservation with nitric acid.

- MS/MSD for Mercury are spiked with 0.25 mL of the 1000 ug/L TCLP Hg spiking solution to 50 mL sample.

- MS/MSD for Metals are spike with 0.50 mL of the solutions listed in Table 4 at the end of this document, according to the elements that are requested, to 50 mL of sample.

9.3.2 The use of internal calibration or alternate methods may be needed when the recovery of the matrix spike is below the expected performance (see Section 9.4.2).

9.3.3 Consult the individual analysis SOPs for additional guidance on spike compounds and levels.

9.4 Corrective Actions

9.4.1 Consult the Laboratory QC Program SOP (PT-QA-021) and individual analysis SOPs for corrective action for QC failures.

9.4.2 Method of Standard Additions (MSA) shall be used for metals if all of the following conditions are met:

- Recovery of the analyte in matrix spike is not at least 50%,

- The concentration of the analyte does not exceed the regulatory level, and

- The concentration of the analyte measured in the sample is within 20% of the appropriate regulatory level.

If the matrix spike recovery is 5% or less due to dilution or matrix interference, contact the project manager and client for guidance. The client should also be contacted prior to initiation of any MSA steps. Refer to the individual analysis SOPs for details on how to perform MSA analysis.

9.4.3 If the temperature during the tumbling procedure is not maintained at 23 ± 2℃ then the samples are required to be re-tumbled. If insufficient sample remains to repeat the tumbling process, the Project Manager will be notified and will call the client for direction on how to proceed.

10. PROCEDURE

10.1 PRELIMINARY SAMPLE EVALUATIONS (Refer to Flow Chart #1, Appendix D)

10.1.1 Preliminary TCLP evaluations (percent solids, particle size, selection of extraction fluid, and fluid/leachate compatibility) are required to be done using a minimum of a 100 gram aliquot of waste. This aliquot may also undergo the actual TCLP or SPLP extraction for Non-volatiles ONLY IF it has NOT been oven dried. If the solid portion is oven dried, a separate aliquot must be used for the actual leaching procedure.

10.1.2 Consult the holding times for the appropriate tests (Section 8.8) and prioritize extractions such that holding times are not exceeded.

10.1.3 All non-aqueous samples must be leached with a minimum100g to 2 L for TCLP and SPLP. The following sample volumes are given to the laboratory for further preparation and analysis after leaching and/or filtration.

Table 2 - Minimum Required Leachate Volume

Analysis	Required Volume (mL)
Volatiles	2 x 40
Semi-volatiles	200
Pesticides	100
Herbicides	100
Metals	150

10.1.3.1 For TCLP and SPLP samples designated or chosen for matrix spike and matrix spike duplicate analysis, three times the listed volumes are required. Spiking is performed after leaching and/or filtration.

10.1.4 SAMPLE DESCRIPTION

10.1.4.1 Observe the number of phases present in the sample according to apparent density. (Note: It may be impossible to distinguish apparent density if only one liquid phase is observed and there is no indication on the COC form. If this is the case, record it as aqueous material and let the subsequent analytical record show if the liquid is organic.) It is common that when more than one container of multi-phasic materials is received from the field, each container will show different amounts of each phase.

10.1.4.2 If the sample has multiple phases and is received in more than 1 bottle then the contents of each bottle should be combined in a single larger container prior to processing the sample further. If this is not possible, then the alternate procedure described in the following section should be used. This procedure is not appropriate if testing will be done for volatile organic compounds.

10.1.4.3 Properly record the relative amounts of each phase by measuring the depth of the layers in each container after the contents have been allowed to settle. Determine the combined volume of each phase for all containers. These values are needed to determine the correct volume/mass adjustments on the final result.

10.1.5 PERCENT SOLID PHASE

10.1.5.1 Percent Solids and ZHE Extractions - The ZHE filtration apparatus cannot accurately determine percent solids less than 5%. If an extraction is to be performed solely for volatile organic compounds and the percent solids concentration is apparently greater than 5%, proceed to Section 10.3 (Procedure: ZHE Extraction Procedure, Volatile Constituents). Otherwise, continue with the steps in this section. The aliquot of sample used here cannot be used again for the ZHE extraction.

10.1.5.2 Determine Type of Filtration Apparatus Needed

- If the waste will obviously yield no free liquid when subjected to pressure filtration (i.e., it is 100% solid), then proceed to Section 10.1.6 (Particle-size Reduction).

- If the sample is mostly a non-viscous liquid (water or non-viscous organic liquid) of low solids content (<10%) or a highly granular, liquid containing waste vacuum filtration may be used.

- If the sample is viscous (sludge or has high solids content), use pressure filtration.

10.1.5.3 Weight of filter - Measure and record this value before loading the filter into the filter holder.

10.1.5.4 Weight of subsample and filtrate for percent solids measurement.

- Assemble the filtration apparatus (use blunt forceps to handle the 0.6 to 0.8 μm filter membrane).

- Homogenize the waste in the sample container. Measure and record the gross weight.

- Measure and record the tare weight of the filtration vessel, screen and filter paper.

- Transfer the sample to the filtration device attempting to spread the waste sample evenly over the surface of the filter. Measure and record the tare weight of the empty sample container and any residual sample.

- Calculate and record the net weight of sample used for testing.

10.1.5.5 Filtration for percent solids

- Slowly apply gentle pressure or vacuum of 10 psi to the filtration apparatus. Allow the sample to filter until no SIGNIFICANT additional liquid has passed through the filter during a 2 minute period.

- Repeat previous step by increasing the pressure in 10 psi increments until a maximum of 50 psi is reached. Stop the filtration when no additional filtrate is generated within a 2 minute period.

Note: Some samples will contain liquid material that does not filter (e.g., oil). Do not attempt to filter the sample again by exchanging filters. Viscous oils or any wastes which do not pass through the filter are classified as a solid.

- Remove the filtrate collection vessel, weigh and record the gross weight.
- Calculate and record the net weight of filtrate. This result will be used in the percent solids calculation.
- Pour the filtrate into a graduated cylinder. Measure and record the volume of the aqueous phase. Measure and record the volume of any organic phase. If more than one organic phase is observed, provide a description. These results will be used in the final sample calculations.
- Retain the filtrate for use in Section 10.1.8 (Determination of Filtrate/Extraction Fluid Compatibility), and for possible recombination with the filtrate obtained in Section 10.2.13.

10.1.5.6 Percent of Wet Solids

- Subtract the net weight of the filtrate `from the net weight of the subsample to calculate the total weight of wet solids.
- Calculate the weight percent of wet solids using the Equation in Section 11.1.1.
- If the percent wet solids result is ≥ 0.5% and < 5.0%, and it is noticed that a small amount of the aqueous filtrate is entrained in the wetting of the filter, proceed to Section 10.1.5.7 to complete the percent solids measurement on a dry-weight basis. **Note:** If obviously oily (non-aqueous) material is entrained on the filter, do not dry the filter; proceed to Section 10.1.7 (Determination of Appropriate Extraction Fluid).
- If the percent wet solids result is greater than 5.0%, proceed to Section 10.1.6 (Particle-Size Reduction).
- If the percent wet solids result is less than 0.5%, the sample is treated as a TCLP/SPLP liquid. Discard the solid phase. No leaching will be necessary; the filtrate is the final TCLP/SPLP leachate.

10.1.5.7 Weight percent of dry solids (skip this step and refer to Appendix B for oily samples). Note: These steps are required only if it is noticed that a small amount of the filtrate is entrained in wetting of the filter and the percent wet solids content is ≥ 0.5% and < 5.0 %

- Remove the filter with the wet solids from the filtration apparatus.
- Dry the filter and solid phase at 100 ± 20 ° C.
- Remove the filter from the oven and allow it to cool in a desiccator.
- Weigh and record the gross dry weight.
- Repeat the drying step. Weigh and record the second gross dry weight. If the two weighings do not agree within 1%, perform additional drying and weighing until successive weighings agree within 1%.
- Calculate the weight percent of dry solids.
- If the dry solids result is ≥ 0.5% and the sample will be extracted for non-volatile constituents, proceed to Section 10.1.6 (Particle Size Reduction) using a fresh wet portion of waste.
- If the percent solids result is less than 0.5%, discard the solid phase. No leaching will be necessary; the filtrate is the TCLP leachate. Proceed to Section 10.1.8 (Determination of Filtrate/Leachate Compatibility) to determine whether or not the material is a non-aqueous, immiscible liquid.

10.1.6 PARTICLE-SIZE REDUCTION FOR FLUID SELECTION

10.1.6.1 This procedure is not applicable to oily or organic liquid samples that are to be treated as a TCLP/SPLP solid.

10.1.6.2 The subsample used for fluid selection must consist of particles less than 1 mm in diameter (versus the less than 1 cm requirement for the material used for the actual extraction). Inappropriate use of coarser materials could result in the selection of the wrong fluid type.

10.1.6.3 Surface area exclusion - size reduction is not required if the sample surface area is greater than or equal to 3.1 cm^2 per gram.

10.1.6.4 If the sample contains particles greater than 1 mm in diameter, crush, cut, or grind the solids to the required size.

10.1.6.5 Consult your supervisor or manager when dealing with unusual sample matrices (e.g., wood, cloth, metal, brick).

10.1.6.6 Equipment blank will be generated when samples undergo particle size reduction. This blank is used to evaluate sieve cleanliness. The blank is generated after the sample goes through the sieve and the sieve is washed and methanol rinsed.

10.1.7 DETERMINATION OF APPROPRIATE EXTRACTION FLUID

10.1.7.1 If the solid content is greater than or equal to 0.5%, and if the sample is being analyzed for metals or nonvolatile organic compounds, the type of leaching solution must be determined.

10.1.7.2 Follow times, temperature, and particle size specified in this section as closely as possible. If reaction time between the acid solution and solid waste is too short or too long, the procedure may produce false pH readings.

10.1.7.3 For SPLP, refer to Section 7.10 for fluid selection. Matrix type must be specified by the client. Check special instructions or see the project manager, then record the fluid type selected on the SPLP worksheet.

10.1.7.4 The TCLP leaching fluid for all volatiles is Fluid #1.

10.1.7.5 For TCLP leach fluid determination for non-volatile analytes, continue with the following steps.

10.1.7.6 Calibrate the pH meter with fresh buffer solutions, using buffers that bracket the anticipated range of samples. (Instructions are for the Accumet XL150 pH meter. If another meter type is used, follow the manufacturer's instructions for calibration.) The meter is calibrated daily with use.

a. Touch **Standardize** on the pH measure screen to access the standardization screen. Touch "**Clear**" to clear the last calibration.

b. Rinse the electrode with reagent water and place in the pH 2.0 buffer. Enter the value (2.0) of the standard into the pH meter using the touch screen, and touch **Enter**. When the reading stabilizes, **STABLE** will appear on the screen. Touch **Confirm** to accept that buffer standardization.

c. Rinse the probe and place it into the 4.0 buffer. Touch **Standardize** to access the standardization screen again, and repeat the steps in b.

d. Repeat b. and c. for 7.0, 10.0 and 13.0 buffers.

e. The Slope of the calibration curve is displayed on the pH Measure screen. The slope must meet the of ≥95% (or other manufacturer's recommended limit) for the calibration to be acceptable.

f. If the slope requirement is not met, clean the probe and repeat calibration with fresh buffers. If the second calibration does not meet the acceptance limit, change the KCl solution in the electrode, and repeat calibration.

g. Each buffer reading must be within 0.05 pH units of the true buffer value. If readings do not meet this requirement, repeat with a second fresh portion of buffer, or repeat the calibration.

h. After the calibration the ICV/LCS, a second source pH 7 buffer, is analyzed before sample analysis. The pH readings must be within 0.05 pH units.

i. Document the calibration and verification in the meter calibration log daily.

10.1.7.7 Weigh out a 5.0 ± 0.1 g subsample (less than 1 mm particle size) of the solid phase into a 250-mL beaker and enter the actual weight on the TCLP worksheet.

10.1.7.8 Add 96.5 ± 1.0 mL of reagent water, cover with a watchglass, and stir for 5 minutes on a stirrer and enter the actual volume on the TCLP worksheet.

10.1.7.9 Measure and record the sample pH. **Note**: To avoid damaging the pH probe when organic liquid (i.e., Oily samples) is present, use narrow range pH indicator paper to determine the pH of this type of sample.

10.1.7.10 If the pH is less than or equal to 5.00, use Fluid #1 and proceed to Section 10.1.8 (Fluid Compatibility).

10.1.7.11 If the fluid pH is greater than 5.0, add 3.5 mL 1 N HCl, cover with a watchglass. Slurry the sample briefly then heat at 50 ^{o}C ± 5°C for 10 minutes. Record the temperature of the hotplate on the TCLP worksheet. **Note**: The heating cycle is a critical step. If the solid waste does not remain in contact with the acidic solution under specified time and temperature conditions, an erroneous pH may be measured.

10.1.7.12 Cool to room temperature.

10.1.7.13 Measure and record the pH immediately after the sample has reached room temperature.

- If the pH is less than or equal to 5.00, use Fluid #1.
- If the pH is greater than 5.00, use Fluid #2.

10.1.8 DETERMINATION OF FILTRATE/EXTRACTION FLUID COMPATIBILITY (skip this step for SPLP extractions)

10.1.8.1 Place 5 mL of the appropriate leaching fluid (determined in the previous step) into a 20-25 mL vial. **Note**: Use fluid type # 1 if simply testing the filtrate for a sample with less than 0.5% solids.

10.1.8.2 Add 5 mL of the initial filtrate, cap and shake.

10.1.8.3 If the phases are miscible, the initial filtrate and solid phase leachate will be physically recombined upon completion of the leachate generation.

10.1.8.4 If the phases are NOT miscible, the initial filtrate and the solid phase leachate will be prepared and analyzed separately and the results mathematically combined (see Section 11.1.4).

10.1.9 For samples requiring analysis for semi-volatile organics, pesticides, herbicides or metals proceed to Section 10.2.

10.1.10 For samples requiring analysis for volatile organics (ZHE), proceed to Section 10.3.

10.2 BOTTLE EXTRACTION PROCEDURE: NON-VOLATILE CONSTITUENTS: SEMI-VOLATILES, PESTICIDES, HERBICIDES, METALS (Refer to Flow Chart #2, Appendix D)

10.2.1 Record all masses to the nearest 0.1 g.

10.2.2 The aliquot used in the Preliminary Evaluation may be used for this procedure only if it was not oven dried. If the sample is 100% solid or if the preliminary aliquot was not oven dried proceed directly to Section 10.2.7 (Particle Size Reduction). If the Preliminary Evaluation aliquot was oven dried then, using a fresh aliquot of sample, continue as described in Sections 10.2.3 through 10.2.6.

10.2.3 Examine the sample and determine the type of filtration to employ per Section 10.1.5.2.

10.2.4 Determine and record the volume (mass) of the initial filtrate. Cover with aluminum foil and retain for use as defined in Section 10.2.13.

10.2.5 Determine and record the "solid" phase mass by subtracting the mass of the liquid filtrate from the mass of the subsample.

10.2.6 Evaluate the solid portion of the waste for particle size. If it contains particles greater than 1 cm in size, prepare the solid portion of the waste for leaching by crushing, cutting, or grinding such that all particles are less than 1 cm in size (i.e., capable of passing through a 9.5 mm, 0.375 inch, standard sieve). Size reduction is not required if the sample surface area is greater than or equal to 3.1 cm^2 per gram.

10.2.6.1 Consult your supervisor or manager when dealing with unusual sample matrices (e.g., wood, cloth, metal, brick). Scissors or shears may be used to cut cloth, plastic or sheet metal. Saws may be used for wood or solid metal. Bricks, rocks, or other solids amenable to grinding should be subcontracted out for particle size reduction. (Contact the assigned Project Manager.) Note that size reduction to fine powder is not appropriate, and could invalidate results. If necessary, consult client for guidance.

10.2.7 Weigh out 100g of solid sample, or the weight required to provide 100g of solid if adjusted for the percent moisture present in the sample.

10.2.8 NOTE: If the solid sample contains 10% moisture that is not filterable liquid, the weight of sample required for 100g of solids is 110g. The corresponding leaching fluid to be added is then reduced for the 10% moisture content of the sample, or 10mL, to 1990mL.

10.2.9 Weigh the required mass of solid phase into an appropriate bottle (plastic for metals only, glass for all others) and slowly add 2000mL, or the volume adjusted for the percent moisture present in the solid sample, of appropriate leaching fluid as determined under Section 10.1.7 (e.g., 100 g of sample would require 2000 g of leaching fluid). Record the weight of the sample aliquoted for the extraction on and the amount of extraction fluid added on the TCLP worksheet.

10.2.9.1 Record the vessel number used for ZHE leaching for each sample on the TCLP worksheet. Note that the same vessel should not be used repeatedly for the method blank, if practical.

10.2.9.2 Vessels are labeled and tracked in a logbook. The date that the vessel is first used and the date it is disposed of are included in this logbook.

10.2.10 Ensure any effervescence has stopped before capping the bottle tightly. Secure in a rotary agitator and rotate end-over-end at 28-32 rpm for 16-20 hours. The temperature of the room must be maintained at 23 ± 2℃ throughout the tumbling period. Start and end times for tumbling are recorded in the TALS batch. The room temperature is monitored using the min/max thermometer that has been set at the beginning of the tumbling period. Both the minimum and maximum temperature of the room during the tumbling period are recorded on the TALS worksheet. The actual tumbler speed (RPM's) will be monitored at the start of each batch and is recorded in the TALS batch information. As agitation continues, pressure may build up within the bottle for some types of wastes. To relieve excessive pressure, the bottle may be removed and opened periodically in a properly vented hood to relieve any built-up pressure.

10.2.11 Remove the bottle and filter the sample using vacuum or pressure filtration by filtering through a new glass fiber filter as discussed in Sections 10.1.5.2. For final filtration of the TCLP/SPLP leachate, the glass fiber filter may be changed, if necessary, to facilitate filtration. Filters must be acid washed if metals are to be determined (see Section 6.3). The entire sample need not be filtered; however, sufficient volume should be generated to support the required analyses. Record the date and time the filtration is started on the TCLP/SPLP worksheet.

10.2.12 If the waste contained no initial filtrate, this solution from 10.2.11 is defined as the TCLP/SPLP leachate.

10.2.13 If the waste did yield an initial filtrate, consult the worksheet for initial filtrate/leachate compatibility. If they are compatible, they are to be combined in the correct proportions (see Section 11.1.4) and mixed well. This combined solution is defined as the TCLP/SPLP leachate.

10.2.14 If the individual phases are NOT compatible, they are to be prepared and analyzed separately and the results combined mathematically. (See Section 11.1.5.)

10.2.15 Measure the pH of the TCLP leachate after filtration and record on the TCLP/SPLP worksheet in TALS. (Do not attempt to measure the pH of oily samples as the probe may be rendered inoperable. Measure the pH of oily samples with pH strips.)

10.2.16 Prepare subsamples for metals for MS/MSD quality control testing using the appropriate TCLP/SPLP spiking solution (do not spike for organics). Record the lot number of the spiking solution on the TCLP/SPLP worksheet. Refer to the

appropriate determinative SOPs for further guidance on the spike components, levels and action criteria.

10.2.17 Immediately preserve the leachate as follows:

- Metals: pH < 2 w/50% HNO_3 for non-oils (do not acidify oils or non-aqueous miscible liquids. Do an NCM along with the batch to let the lab and PM know the sample was not preserved.)
  - o All metals aliquots other then the MS and MSD volumes shall be filtered into a pre-preserved 125mL bottle containing nitric acid.
  - o The preservation pH shall be checked by dripping a few drops of the preserved sample onto acid-range pH paper. The pH of the preserved leachate must be ≤2.
  - o MS and MSD volumes are spiked according to section 9.3, and then preserved with nitric acid to pH ≤2. Start by adding 0.5mL concentrated nitric acid to the spiked sample, add an additional 0.5mL if the pH is not ≤2.
  - o Document the preserved pH in the comment column of the TALS batch.

- All other parameters: Refrigerate to >0.0˚C but ≤6.0˚C

Note: Refer to Section 8.7 if precipitation occurs upon preservation.

10.2.18 Label each sample with the appropriate information and submit to the appropriate analytical groups for leachate extraction/digestion and analysis with copies of the TCLP preparation worksheets.

10.3 ZHE EXTRACTION PROCEDURE: VOLATILE CONSTITUENTS (Refer to Flow Chart #3, Appendix D)

10.3.1 Use the ZHE device to obtain a TCLP/SPLP leachate for analysis of volatile compounds only. Leachate resulting from the use of the ZHE shall NOT be used to evaluate the mobility of non-volatile analytes (e.g., metals, pesticides, etc.).

10.3.2 Due to some shortcomings of the method, losses of volatile compounds may occur. Extra care should be observed during the ZHE procedure to ensure that such losses are minimized. Charge the ZHE with sample only once and do not open the device until the final extract has been collected. Do not allow the waste, the initial liquid phase or the extract to be exposed to the atmosphere any longer than necessary.

10.3.3 If the TCLP/SPLP extraction is for volatile components only, refer to Section 10.1.5.1 before proceeding.

10.3.4 All masses should be recorded to the nearest 0.1 g.

10.3.5 Assemble the ZHE apparatus. Test for leakage by closing all valves except the gas inlet/outlet valve and pressurizing to 50 psi. Allow to stand for 15 minutes and check the pressure on the built-in gauge to make sure it is not leaking. If the pressure is NOT 50 psi, consult your supervisor.

10.3.6 Adjust the ZHE piston in the ZHE body to the appropriate height (slightly moisten the O-rings with leaching fluid if necessary).

10.3.7 Consult the backlog for matrix designation and examine the sample. If the sample appears to be different from the preliminary information found on the backlog, consult your supervisor.

10.3.8 If the preliminary evaluations indicated the need for particle size reduction, homogenize the waste, weigh out a sufficient size subsample and prepare for leaching by crushing, cutting, or grinding such that all particles are less than 1 cm in size as measured with a ruler (Do NOT sieve the sample). Size reduction is not required if the sample surface area is greater than or equal to 3.1 cm^2 per gram. **Note:** To minimize loss of volatiles, samples for volatiles that require particle size reduction should be kept in sample storage (>0.0 ºC but ≤6.0°C) until immediately before size reduction. Aggressive reduction, which would generate heat, should be avoided and exposure of the waste to the atmosphere should be avoided to the extent possible. Size reduction to a fine powder is not appropriate.

10.3.8.1 Consult your supervisor or manager when dealing with unusual sample matrices (e.g., wood, cloth, metal, brick). Scissors or shears may be used to cut cloth, plastic or sheet metal. Saws may be used for wood or solid metal. Bricks, rocks, or other solids amenable to grinding should be subcontracted out for particle size reduction.

10.3.9 Place the ZHE apparatus on the balance and tare the balance.

10.3.10 Determine the appropriate size subsample to weigh using the percent solids information from Section 10.1.5, based on 25 g of solid.

10.3.10.1 For wastes that are 100% solids, a 25 g sample is used.

10.3.10.2 For wastes containing < 0.5% solids the liquid portion of the waste, after filtration, is defined as the TCLP/SPLP leachate. Filter enough of the sample to support all of the volatile analyses required.

10.3.10.3 For wastes containing ≥ 0.5% and < 5.0% solids, a 500 g subsample of waste is recommended.

10.3.10.4 If the sample has ≥ 5.0% solids, the appropriate sample size should be determined using the equation in Section 11.2. **Note:** For wastes containing greater than 0.5% wet or dry solids (Section 10.1.5), the "solids" value from the ZHE filtration process may be used to determine the volume of fluid to load into the ZHE. This approach is recommended since the solids value from Section 10.1.5 may differ from the filtration solids due to sample variability or differences in the filtration apparatus.

10.3.11 Homogenize and transfer an appropriate size subsample of the waste into the ZHE and record the mass.

10.3.12 Carefully place the glass fiber filter between the support screens and secure to the ZHE. Tighten all the fittings.

10.3.13 Place the ZHE in a vertical position; open both the gas AND liquid inlet/outlet valves. Attach a gas line to the gas inlet/outlet valve.

10.3.14 If the waste is 100% solid, slowly increase the pressure to a maximum of 50 psi to force out as much headspace as possible and proceed to Section 10.3.19.

10.3.15 If the waste is < 100% solids, carefully apply gentle pressure of 10 PSI (or more, if necessary) to force all headspace slowly out of the ZHE. At the FIRST appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue gas pressure.

10.3.16 Assemble a syringe and place the plunger in all the way. Adjust the tension on the plunger to provide slight drag. Attach the pre-weighed syringe or Tedlar bag to the liquid inlet/outlet valve and open the valve. Record the tare weight of the collection device.

10.3.17 Carefully apply gas pressure of no more than 10 PSI to force out the liquid phase. Allow the sample to filter until no SIGNIFICANT additional filtrate has passed in a 2 minute period. **Note**: If the capacity of the syringe is reached, close the liquid inlet/outlet valve, discontinue gas pressure, remove the syringe and return to Section 10.3.15.

10.3.18 Repeat previous step increasing the pressure in 10 PSI increments until 50 PSI is reached and no significant liquid has passed in a 2 minute period. Remove the collection device and record the total weight of the collection device with filtrate. Close the valve and discontinue gas pressure. Transfer the filtrate to VOA vials and label appropriately. Calculate the weight of filtrate collected. **Notes:** If the original waste contained less than 0.5% solids (Section 11.2.5), this filtrate is defined as the TCLP/SPLP leachate and you may proceed to

Section 10.3.28. Otherwise, save the vials by storing at 4 C under minimal headspace conditions, for recombination as in Section 10.4.27. The material remaining in the ZHE is defined to be the "solid" phase. Calculate the weight of the solid phase.

10.3.19 Based on the information from Sections 10.1.5 and 10.3.10 and using the formula in 11.1.3, determine the weight of fluid to load into the ZHE on the "solid" phase. The ZHE device has approximately a 500-mL capacity. Based on the need to add an amount of extraction fluid equal to 20 times the mass of the "solid" phase, the ZHE can therefore accommodate a maximum of 25 grams of "solid". **Note:** The TCLP ZHE prep uses only TCLP fluid #1; the SPLP ZHE prep uses only DI Water.

10.3.20 Load the fluid transfer reservoir with an excess of Fluid #1 for TCLP or DI Water for SPLP and preflush the transfer line to eliminate air pockets. Be sure the required volume remains.

10.3.21 Using a stainless steel syringe transfer the required volume into the ZHE and close the valve.

10.3.22 Check the ZHE to make sure all the valves are closed and manually rotate the ZHE (end-over-end) 2 or 3 times. Reposition the ZHE in the vertical position.

10.3.23 Pressurize the ZHE to 5-10 PSI. Allow to stand for 10 minutes, and then recheck the pressure. If the ZHE appears to be leaking, follow the corrective action protocols recommended by the manufacturer and repeat the test.

10.3.24 Slowly open the liquid inlet/outlet valve to bleed out any headspace that may have been introduced during the introduction of the Fluid. Upon the first sign of liquid from the valve, close the valve.

10.3.25 Repressurize the ZHE to 5-10 PSI and place in the rotary agitator. Rotate at 28-32 rpm for 16-20 hours. Room temperature should be 23 ± 2 ℃. The room temperature and time should be checked at both the start and end of the extraction and recorded on the ZHE worksheet.

10.3.26 Confirm that the pressure of 5-10 PSI was maintained throughout the leaching. If it was not maintained, return to Section 10.3.1 and repeat the leachate with a new aliquot of sample. Contact the PM if there is insufficient sample to repeat the leaching procedure.

10.3.27 Attach a syringe or Tedlar bag and open the liquid inlet/outlet valve to collect the aqueous leachate and proceed as outlined in 10.3.19 - 10.3.20. Record the volume/mass of the leachate and any oil phase. Record the date and time the

filtration is completed on the ZHE worksheet. **Note:** If the waste contained an initial liquid phase, the liquid may be filtered directly into the same collection device holding the initial liquid phase of the waste. A separate filtrate collection container must be used if combination would create multiple phases or there is not enough volume left within the filtrate collection container.

10.3.28 If the waste contained an initial filtrate (Section 10.3.18) that is miscible with the solid phase leachate (as determined in Section 10.1.8), the solid phase leachate and the initial filtrate are directly recombined in the correct proportions (see Section 11.1.4). If the individual phases are NOT compatible, they are to be collected, prepped and analyzed separately. **Note:** Chill the filtrate and receiving vessels before recombining.

10.3.29 Following collection, store the TCLP/SPLP leachate in 2 40-mL VOA vials with minimal headspace at 4 ± 2 °C and prepare for analysis as soon as possible using the appropriate organic extraction procedure. Due to space limitations, the rest of the leachate is disposed of.

10.3.30 If the individual phases are analyzed separately, combine the results mathematically by using the recombination calculation in Section 11.1.5.

11. CALCULATIONS/DATA REDUCTION

11.1 Calculation of Percent Wet Solids:

$$Percent\ \ Wet\ \ Solids = 100\left(\frac{Mass,"solid"\ phase}{Mass,initial\ subsample}\right)$$

11.2 Calculation of weight of waste to charge to ZHE:

$$Weight\ of\ \ waste\ to\ charge\ to\ ZHE = 100\left(\frac{25}{\%\ wet\ solids}\right)$$

11.3 Calculation of weight of extraction fluid to use:

$$Weight\ of\ \ Extraction\ \ fluid = \frac{20\ x\ \%\ wet\ solids\ x\ weight\ of\ \ waste\ to\ be\ extracted}{100}$$

11.4 Calculation of volume of initial filtrate phase to recombine with solid phase leachate:

$$\text{Volume of filtrate for recombination} = \left(\frac{Weight\ of\ solids\ leached}{Total\ weight\ of\ solids}\right)\left(\frac{Leachate\ recovered}{Fluid\ added}\right)\left(Volume\ of\ initial\ aqueous\ filtrate\right)$$

11.5 Mathematical recombination of analytical results:

$$Final\ Analyte\ Concentration = \frac{(V_1 \times C_1) + (V_2 \times C_2)}{V_1 + V_2}$$

V_1 = total volume of the initial filtrate phase (L).
C_1 = analyte concentration in initial filtrate phase (mg/L).
V_2 = volume of the theoretical solid phase leachate (L).
C_2 = analyte concentration in solid phase leachate (mg/L).,

11.6 REPORTING REQUIREMENTS

11.6.1 Samples generated with method deviations, such as temperature exceedances, insufficient sample for TCLP/SPLP complaint tumble, etc…, must be reported as **NOT** TCLP/SPLP compliant through an NCM and narrated in the Case Narrative of the final report.

11.6.2 Follow these reporting conventions for multi-phase samples:

11.6.2.1 If both phases have positive results, use the values from each phase to calculate the recombined result. Use the reporting limit for each phase to calculate the recombined reporting limit.

11.6.2.2 If both phases are “ND,” not detected, the recombined result is “ND,” and the reporting limit is calculated from the reporting limit for each phase.

11.6.2.3 If one phase is “ND” and the other phase has a positive result, use the reporting limit for the “ND” phase and the positive value for the other phase to calculate the combined result. The combined reporting limit is based on the reporting limit for both phases. If the combined result is less than the combined reporting limit, then supply a footnote to indicate that “a positive result was detected below the calculated detection limit.”

11.6.3 Units - regardless of the nature of the sample, all TCLP and SPLP results are reported in units of mg/L.

11.6.4 For limits and significant figures, consult the appropriate analytical methods.

11.6.5 Anomalies - all anomalies observed during the leach procedure must be noted on the worksheet or an anomaly form. Some examples of such anomalies are:

11.6.5.1 Sample was monolithic - subsample was obtained by crushing, cutting, grinding, sawing, etc.

11.6.5.2 Insufficient sample - less than the required 100 g minimum was available.

11.6.5.3 If less than the required minimum sample is available, the client will be contacted to determine whether or not to proceed with the extraction. If the client chooses to proceed, an explanation will be included in the Case Narrative.

11.6.5.4 Multiple phases - "X" phases were present.

11.6.5.5 Sample was oil - single phase.

11.6.5.6 Sample contained liquid that did not filter under test conditions.

11.7 REVIEW REQUIREMENTS

11.7.1 Review all applicable holding times. If a holding time was exceeded, confirm that a holding time violation form was properly documented and routed.

11.7.2 If Total analysis results are available, those results may be compared with the TCLP/SPLP analysis results according to the following:

$$Total \geq 20 \times TCLP/SPLP$$

NOTE: Assumes the sample is 100% Solids.

11.7.3 Total constituent analysis results can be used to demonstrate the TCLP/SPLP protocol is unnecessary. In performing a TCLP/SPLP analysis, there is a 20x dilution of the original sample with the leaching solution. Thus, if the "total constituent" result is less than 20 times the TCLP/SPLP action level, it is impossible for the leachate to "fail" and the TCLP/SPLP does not need to be performed. For example, the TC level for lead is 5.0 mg/L (ppm). Therefore, if a sample of lead-contaminated soil contains less than 100 ppm total lead, a TCLP/SPLP test need not be run for lead.

12. METHOD PERFORMANCE

12.1 The supervisor has responsibility to ensure that an analyst who performs this procedure is properly trained in its use and has the required experience. Performance is monitored through internal QC and outside performance evaluation samples. Please refer to the QA Manual (PT-QA-M-001) for additional information concerning Precision and Accuracy.

12.2 Demonstration of Capability – Prior to the independent analysis of client samples, A Demonstration of Capability (DOC), as described in the QA Manual, must be performed. DOCs are repeated annually and any time a significant change is made to the analytical system.

12.3 TCLP/SPLP leaching is not included in MDL studies.

13. POLLUTION PREVENTION

13.1 It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Environmental Health and Safety Manual (CW-E-M-001) for "Waste Management and Pollution Prevention" and the Pittsburgh Facility Addendum EH&S Manual (PT-HS-001).

13.2 This method does not contain any specific modifications that serve to minimize or prevent pollution.

14. WASTE MANAGEMENT

14.1 Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to PT-HS-001. The following waste streams are produced when this method is carried out.

14.1.1 Remaining TCLP/SPLP extracts: Fluid is collected in a Hazardous Water Drum, Waste #24.

14.1.2 Solids: This waste includes soils, filter paper, paper towels, etc. This waste is collected in containers identified as "Lab Trash", Waste #12.

16. METHOD MODIFICATIONS

16.1 Section 10.1.1: Preliminary Evaluations. Section 7.1 of source method SW846 1311 states that the sample aliquot used for the preliminary evaluation "...may not actually undergo TCLP extraction." Section 7.1.5 of the source method indicates that the portion used for the preliminary evaluation may be used for either the ZHE or non-volatile extraction if the sample was 100% solid. Section 7.1.5 further indicates that if the sample was subjected to filtration (i.e., < 100% solid) that this aliquot may be used for the non-volatile extraction procedure only as long as sufficient sample is available (minimum 100 g). Samples which have been subjected to the ovendrying step may not be used for TCLP extraction because solid phase degradation may result upon heating.

16.2 Section 10.1.5.6: Percent Solids Determination. Section 7.1.2 of source method SW846 1311 indicates that "if the percent wet solids is ≥ 0.5% and it is noticed that a small amount of the filtrate is entrained in wetting of the filter" that the filter should be oven dried to determine percent dry solids ". Drying of oil or organic matrices can both

be hazardous and inappropriate. Additionally, it may be impossible to achieve a constant weight when performing this step. Due to safety concerns, if obviously oily or heavy organic matrices are entrained on the filter, the filter is not oven dried.

16.3 Section 10.1.8: Preliminary Determination of Filtrate/Extraction Fluid Compatibility. Section 7.2.13 of the source method SW846 1311 provides no guidance as to how to make this determination. As a result, the procedure herein was developed and incorporated into the Preliminary Determinations section.

16.4 Section 9.2: TCLP/SPLP Extraction Blanks. Section 8.1 of the source methods state that a minimum of one blank for every 20 extractions "...that have been conducted in an extraction vessel." TestAmerica has interpreted this to mean one blank per twenty samples leached per TYPE of leaching vessel (i.e., Bottle or ZHE) per leach fluid used. Only ZHEs are tracked, as bottles used for other tumbling are not re-used.

16.5 Section 10.1.7.10: Determination of Appropriate Extraction Fluid. SW846 Method 1311 does not address the appropriate approach to take if the pH equals 5.0. This SOP requires that Fluid #1 must be used if the pH is less than or equal to 5.0.

16.6 Section 9.3: QA/QC - Matrix Spikes. Section 8.2 of the source method SW846 1311 states "A matrix spike shall be performed for each waste type..." and "A minimum of one matrix spike must be analyzed for each analytical batch." Further, Section 8.2.3 of the source method also states "The purpose of the matrix spike is to monitor the performance of the analytical methods used, and to determine whether matrix interferences exist." The standard TestAmerica QAPP is designed to address the performance monitoring of analytical methodology through the LCS program. A minimum of one MS and MSD will be prepared for each TCLP/SPLP leachate batch. The MS/MSD results are used to determine the effect of a matrix on the precision and accuracy of the analytical process. Due to the potential variability of the matrix of each sample, the MS/MSD results have immediate bearing only on the specific sample spiked and not all samples in the batch.

16.6.1 Section 8.2.2 of the source method states that "In most cases, matrix spikes should be added at a concentration equivalent to the corresponding regulatory level." The method also states "If the analyte concentration is less than one half the regulatory level, the spike concentration may be as low as one half of the analyte concentration but may not be less than five times the method detection limit". For several analytes, spiking at the regulatory level is inappropriate to the range of analysis afforded by the determinative methods. Due to the wide range in these levels, TestAmerica spikes at the levels specified in the determinative SOPs.

OFFICE OF
SOLID WASTE AND EMERGENCY RESPONSE

MEMORANDUM # 35

DATE: June 12, 1992

SUBJECT: Notes on RCRA Methods and QA Activities

From: Gail Hansen, Chief
Methods Section (OS-331)

This memo addresses the following topics:

- o 1992 Symposium on Waste Testing and Quality Assurance
- o SW-846 Update
  - Final Rule for January 23, 1989 Proposed Rule
  - Notice, Proposed Rulemaking for the Second Update to the Third Edition
- o Chlorofluorocarbon 113 (CFC-113) Solvent Replacement Update
- o Environmental Monitoring Methods Index (EMMI)
- o Sampling Work Group Formation
- o MICE Update
- o Oily Waste Analysis
- o Electronic SW-846 Availability.

Printed on Recycled Paper

Figure 3 - US Environmental Protection Agency Memorandum #35, Page 10

Oily Waste Analysis

One of the most frequently asked questions on the MICE Service concerns the application of the TCLP, Method 1311, to oily wastes. Many callers request technical guidance on the extraction of oily wastes due to the difficulty in the filtration on these types of waste. In many cases, an oily waste does not filter completely due to premature clogging of the glass fiber filter. This can result in the retention of standing liquid on the glass fiber filter. Material that do not pass through the glass fiber filter at the conclusion of the filtration step is defined by the method as the solid phase of the waste. The solid phase is then subjected to the leaching procedure of the TCLP. For oily wastes, clogging of the glass fiber filter can result in an overestimation of the amount of solid material available for leaching.

To solve this problem, the Agency recommends a conservative approach, one that probably will overestimate the amount of leaching. Rather than performing the TCLP extraction on the unfiltered portion of the oily waste, assume the waste is 100% liquid (e.g., will pass through the glass fiber filter) and perform a totals analysis on the oily waste to determine if the oil exceeds the appropriate regulatory level.

Filterable waste oil generated during the TCLP must be analyzed for a variety of organic and inorganic analytes. The OSW recognizes the difficulty in achieving acceptable performance for the analysis of waste oil using methods currently provided in SW-846. As a result, the Agency will provide several new methods for the preparation and analysis of oil samples to the Organic Methods Workgroup in July. In addition, a microwave assisted digestion procedure should improve the analysis of metals and will be proposed as part of the Second Update of the Third Edition of SW-846. Brief descriptions of these techniques are provided below, for additional information on the organic procedures contact Barry Lesnik at (202) 260-7459. For additional information on microwave digestion contact Ollie Fordham (202) 260-4778.

The use of purge-and-trap (Method 5030) for volatiles in oil generally results in severe contamination of analytical instrumentation. Traps, transfer lines and chromatography columns may become contaminated with oil. This leads to elevated baselines, hydrocarbon background in subsequent analyses, and cross-contamination. Headspace (Method 3810) is currently allowed only as a screening procedure in SW-846. The Agency is evaluating the use of headspace in conjunction with isotope dilution mass spectrometry for the quantitative analysis of volatiles in oil. Headspace reduces interference problems encountered with purge-and-trap. However, headspace quantitation can be questionable because the distribution of analytes is not

1.0 Scope and Application

This SOP gives the procedures for the determination of various analytes in water and soil samples using the Konelab Autoanalyzer. The following analytes may be determined:

Analyte	Reference Method	SOP Summary
Ammonia	EPA 350.1 SM4500-NH3 B (AQ prep) COE 3-154 (SO Prep) SM4500-NH3 G (analysis)	Attachment 1a
Chloride	EPA 325.2 EPA 9251 SM4500-Cl^- E	Attachment 1b
Total Chlorine	EPA 5050 / EPA 9251	Attachment 1b
Ferrous iron	SM3500-Fe D (SM 21st Edition) SM3500-Fe B (SM On-Line Edition)	Attachment 1c
Ferric Iron	SM3500-Fe B (Calculation)	Attachment 1c
Hexavalent Chromium	EPA 7196A SM3500-Cr D (SM 21st Edition) SM3500-Cr B (SM On-Line Edition)	Attachment 1d
Trivalent Chromium	EPA 7196A SM3500-Cr B (Calculation)	Attachment 1d
Ortho-Phosphate	EPA 365.1 SM4500-P F	Attachment 1e
Sulfate	EPA 375.4 EPA 9038	Attachment 1f
Total Sulfur	EPA 5050 / EPA 9038	Attachment 1f
BTU	ASTM D240-87	Attachment 1f

The reporting limits (RL), the method detection limits (MDL), and the accuracy and precision criteria associated with each method are provided in the TALS Method Limit Groups (MLGs).

This SOP was written by and for Eurofins Savannah laboratory.

2.0 Summary of Method

Samples and reagents are dispensed into disposable, acrylic multi-cell cuvettes that hold 12 separate analyses. During the incubation period(s), the sample cuvettes are maintained at 37°C. The measurement system is a single channel interference filter photometer with beam splitting reference. The color wheel can be configured with up to 15 different filters. Fiber optic cabling transfers the light signal from the source to the detector. The lamp is a halogen lamp.

The SOP Attachments contain the method parameters required to perform each analysis, a summary of the "chemistries" (reagents, standards, procedures, wavelengths, etc.) used to measure each target analyte, sample preparation information, as well as any method-specific information, requirements, and/or criteria. Method-specific requirements contained in the Attachments supersede the requirements outlined within the body of this SOP.

This SOP is based on the methods listed in Section 1.0.

3.0 Definitions

Refer to the Glossary Section of the *Quality Assurance Manual* (QAM) for a complete listing of applicable definitions and acronyms.

4.0 Interferences

4.1 Procedural Interferences

4.1.1 Interferences may be caused by contaminants in solvents, reagents, glassware, and other sample processing apparatus and can make identification and/or quantification of the target analytes difficult.

4.1.2 All sample collection containers are single-use disposable containers which limits the potential for contamination. All non-disposable labware must be scrupulously cleaned in accordance with the posted Labware Cleaning Instructions to ensure it is free from contaminants and does not contribute artifacts.

4.1.3 High purity reagents and solvents are used to help minimize interference problems. Acetone, hydrochloric acid, methanol, nitric acid, and sulfuric acid must be verified prior to use in accordance with the Eurofins Environment Testing Solvent Lot Testing Program.

4.1.4 Instrument and/or method blanks are routinely used to demonstrate all reagents and apparatus are free from interferences under the conditions of the analysis.

4.1.5 Refer to the appropriate SOP Attachment, as listed in Section 1, for any method-specific procedural interference information.

4.2 Matrix Interferences

4.2.1 Matrix interferences may be caused by contaminants that are co-extracted from the sample matrix. The sample may require cleanup or dilution prior to analysis to reduce or eliminate the interferences. For this procedure, the only cleanup procedure available is filtration through a 0.45um filter. This filtration step will remove turbidity that is present that may interfere with analysis.

4.2.2 Interfering contamination may occur when a sample containing low concentrations of analytes is analyzed immediately following a sample containing relatively high concentrations of analytes. As such, samples known to be clean should be analyzed first. To prevent carryover into subsequent samples, analysis of reagent blanks may be needed after the analysis of a sample containing high concentrations of analytes.

4.2.3 Refer to the appropriate SOP Attachment, as listed in Section 1, for any method-specific matrix interference information.

5.0 Safety

Employees must abide by the policies and procedures in the Eurofins Environment Testing Environmental Health and Safety Manual (EHSM), the Eurofins Savannah Addendum to the EHSM, and this document.

This procedure may involve hazardous materials, operations, and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user to follow appropriate safety, waste disposal, and health practices under the assumption that all samples and reagents are potentially hazardous.

The analyst must protect himself/herself from exposure to the sample matrix. Many of the samples that are tested may contain hazardous chemical compounds or biological organisms. The analyst must, at a minimum, wear protective clothing (lab coat), eye protection (safety glasses or face shield), disposable nitrile gloves, or equivalent, and closed-toe, nonabsorbent shoes when handling samples.

5.1 Specific Safety Concerns or Requirements

The toxicity or carcinogenicity of chemicals used in this method has not been precisely defined. Each chemical should be treated as a potential health hazard, and exposure to these chemicals should be minimized.

Mercuric thiocyanate will give off hydrogen cyanide (HCN) gas if combined with strong acids. Inhalation of CN gas can cause irritation, dizziness, nausea, unconsciousness and potentially death.

Sulfuric acid is a strong oxidizer and is a corrosive. It will react violently when combined with organic compounds, possibly producing fire. Inhalation can cause irritation of the

nose, throat, mucus membranes, and upper respiratory tract. Contact with the eyes can cause blurred vision, redness, pain, and even blindness.

Acetic acid is a corrosive. Contact with concentrated acetic acid can cause damage to the skin and eyes. Inhalation of concentrated vapors may cause damage to the lining of the nose, throat, and lungs.

Acetone is a flammable solvent. It can cause irritation to the respiratory tract. Overexposure can cause fatigue, lightheadedness, headache, dizziness, and blurred vision.

Nitric and hydrochloric acids are extremely hazardous as oxidizers, corrosives, poisons, and are reactive. Inhalation of the vapors can cause coughing, choking, irritation of the nose, throat, and respiratory tract, breathing difficulties, and lead to pneumonia and pulmonary edema. Contact with the skin can cause severe burns, redness, and pain. Nitric acid can cause deep ulcers, and staining of the skin to a yellow or yellow-brown color. These acid vapors are irritating and can cause damage to the eyes. Contact with the eyes can cause permanent damage.

Methanol is a flammable solvent. It can cause irritation to the respiratory tract. Overexposure can cause fatigue, confusion, headache, dizziness, and drowsiness.

5.2 Primary Materials Used

The following is a list of the materials used in this procedure, which have a serious or significant hazard rating, and a summary of the primary hazards listed in their MSDS/SDS.

NOTE: This list does not include all materials used in the procedure. A complete list of materials used in this procedure can be found in the Reagents and Standards Section and the Equipment and Supplies Section of this SOP

Employees must review the information in the MSDS/SDS for each material before using it for the first time or when there are major changes to the MSDS/SDS. Electronic copies of MSDS/SDS can be found using the “MSDS” link on the Oasis homepage, on the EH&S webpage on Oasis, and via TALS File System Shares.

Material	Hazards	Exposure Limit[1]	Signs and Symptoms of Exposure
Acetic Acid	Corrosive Poison Flammable	10ppm TWA	Contact with concentrated solution may cause serious damage to the skin and eyes. Inhalation of concentrated vapors may cause serious damage to the lining of the nose, throat, and lungs. Breathing difficulties may occur.
Acetone	Flammable	1000ppm TWA	Inhalation of vapors irritates the respiratory tract. May cause coughing, dizziness, dullness, and headache.
Barium Chloride	Poison Irritant	0.5mg/m^3 TWA	May be fatal if swallowed. Harmful if inhaled. Avoid contact with eyes, skin, and clothing. Avoid breathing dust. Keep container closed and when in use adequate ventilation.
Ferric Nitrate	Oxidizer	None	Causes irritation to the respiratory tract. Causes irritation, redness, and pain to the skin and eyes.
Hydrochloric Acid[2]	Corrosive Poison	5ppm Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failure, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Mercuric Thiocyanate	Poison	0.1 mg/m^3 Ceiling (Mercury Compounds)	Extremely Toxic. Causes irritation to the respiratory tract. **May produce Hydrogen Cyanide gas if combined with strong acids.** Causes irritation. Symptoms include redness and pain. May cause burns. May cause sensitization. Can be absorbed through the skin with symptoms to parallel ingestion. **May affect the central nervous system.** Causes irritation and burns to eyes. Symptoms include redness, pain, and blurred vision; may cause serious and permanent eye damage.
Methanol	Flammable Poison Irritant	200ppm TWA	A slight irritant to the mucous membranes. Toxic effects exerted upon nervous system, particularly the optic nerve. Symptoms of overexposure may include headache, drowsiness and dizziness. Methyl alcohol is a defatting agent and may cause skin to become dry and cracked. Skin absorption can occur; symptoms may parallel inhalation exposure. Irritant to the eyes.

Material	Hazards	Exposure Limit[1]	Signs and Symptoms of Exposure
Nitric Acid[2]	Corrosive Oxidizer Poison	2ppm TWA 4ppm STEL	Nitric acid is extremely hazardous; it is corrosive, reactive, an oxidizer, and a poison. Inhalation of vapors can cause breathing difficulties and lead to pneumonia and pulmonary edema, which may be fatal. Other symptoms may include coughing, choking, and irritation of the nose, throat, and respiratory tract. Can cause redness, pain, and severe skin burns. Concentrated solutions cause deep ulcers and stain skin a yellow or yellow-brown color. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Phenol	Corrosive	5ppm TWA	Breathing vapor, dust or mist results in digestive disturbances. Will irritate and possibly burn respiratory tract. Rapidly absorbed through the skin with systemic poisoning effects to follow. Discoloration and severe burns may occur, but may be disguised by a loss in pain sensation. Eye burns with redness, pain, blurred vision may occur. May cause severe damage and blindness.
Phosphoric Acid	Corrosive	1mg/m^3 TWA	Inhalation is not an expected hazard unless misted or heated to high temperatures. May cause redness, pain, and severe skin burns. May cause redness, pain, blurred vision, eye burns, and permanent eye damage.
Sodium Hydroxide	Corrosive Poison	2mg/m^3 TWA	This material will cause burns if comes into contact with the skin or eyes. Inhalation of Sodium Hydroxide dust will cause irritation of the nasal and respiratory system.
Sulfuric Acid[2]	Corrosive Oxidizer Dehydrator Poison Carcinogen	1mg/m^3 TWA	Inhalation produces damaging effects on the mucous membranes and upper respiratory tract. Symptoms may include irritation of the nose and throat, and labored breathing. Symptoms of redness, pain, and severe burn can occur. Contact can cause blurred vision, redness, pain and severe tissue burns. Can cause blindness.
[1]Exposure limit refers to the OSHA regulatory exposure limit.			
[2]Always add acid to water to prevent violent reactions.			

6.0 Equipment and Supplies

All applicable laboratory support equipment and supplies (including balances; thermometers; and volumetric containers, used to determine quantitative measurements, such as mechanical pipettes, disposable graduated pipettes, gas-tight syringes, etc.) must be verified in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*.

6.1 Equipment and Instrumentation

- Top-loading Balance
- Tumbler
- MicroDist Apparatus
- Konelab Model 20 Autoanalyzer, or equivalent
- Data System: The software system is based on the Windows NT operating system. The hardware interface can be either RS232 or an Ethernet connection and can be integrated to both transmit and receive information from a TALS.

6.2 Analytical Data System/ Software / Hardware

The Quality Assurance Department maintains the Master Equipment Listing for the laboratory. This is a listing of all instrumentation utilized by the laboratory and includes details about the instrumentation including the software or firmware.

6.3 Volumetric Containers and Dispensers

All volumetric labware must be verified in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use).* Refer to Attachment 6 for Labware Cleaning Procedures.

Volumetric Labware	Volume	Type (Quantitative / Qualitative)	Use	Verification Frequency	Laboratory Verification Criteria
Plastic Transfer Pipettes	Various	Qualitative	pH checks, transferring sample or reagents	None	None
Disposable Medicine Cups	Various	Qualitative	Used to contain sample aliquot for pH measurement	None	None
Disposable Konelab Sample Cups	2mL	Qualitative	Holding sample on instrument	None	None
Eppendorf-Style Mechanical Pipettes	Various	QUANTITATIVE	Preparing Dilutions, Standard and Reagent Preparation and Spiking	Initially, prior to first use, then quarterly thereafter (Daily for DOD)	Accuracy = 2% Precision = 1%
Volumetric Flasks (Class A)	Various	QUANTITATIVE	Preparing Dilutions, Standard and Reagent Preparation	None (Class A)	None (Class A)
Graduated Cylinders (Class A)	Various	QUANTITATIVE	Preparing Dilutions, Standard and Reagent Preparation	None (Class A)	None (Class A)
Disposable Round Bottom Test Tubes	8mL	Qualitative	Holding sample on instrument	None	None

6.4 Lab Supplies

- pH paper (narrow and wide range)
- Residual Chlorine Check Strips – starch iodide strips or DPD pillow pops
- Detergent – Nochromix, or equivalent, used for washing non-disposable labware.
- Hengar Granules
- Magnetic Stir Bars
- Teflon Chips – used as soil blank matrix

6.5 Sample Collection Containers

All sample collection containers are single-use disposable containers which limits the potential for contamination. The routine sample collection containers supplied by the laboratory are purchased with Certificate of Analysis attesting to purity.

Refer to Attachment 2 for a cross-reference of containers to methods.

7.0 Reagents and Standards

7.1 Expiration Dates

Expiration dates (time from initial use or receipt to final use) for standard and reagent materials must be set according to the guidance in this SOP. Note: These are maximum expiration dates and are not to be considered an absolute guarantee of standard or reagent quality. Sound judgment must be used when deciding whether to use a standard or reagent. If there is doubt about the quality of a standard or reagent material, a new material must be obtained or the standard or reagent material verified. Data quality must not be compromised to extend a standard's life.

The expiration date of any standard or reagent must not exceed the expiration date of the standard or reagent that was used to prepare it.

Unless noted elsewhere in this SOP, the following expiration date requirements and storage conditions apply:

Purchased Unopened = Manufacturer's Expiration Date
Purchased Opened = 5 years from Open Date
Prepared = 3 months from Preparation Date
Storage = Room Temperature

7.2 Reagents

Reagents must be prepared and documented in accordance with SOP SA-AN-041: *Reagent and Standard Materials Procedures.* Certificates of analysis or purity must be received with all purchased reagents, and scanned and attached to the standard in TALS. Unless otherwise stated in the method-specific attachments, reagents should be stored in a cool, dry, ventilated storage area away from incompatible materials.

Refer to the appropriate SOP Attachment, as listed in Section 1, for the method-specific reagents associated with each analysis.

Acetone, hydrochloric acid, methanol, nitric acid, and sulfuric acid must be verified prior to use in accordance with the Eurofins Environment Testing Solvent Lot Testing Program.

Blank Matrix – Ottawa Sand or Teflon Chips (see associated Attachment). Used for the preparation of soil QC samples.

Laboratory Reagent Water – ASTM Type II (also referred to as DI Water)

7.3 Standards

Standards must be prepared and documented in accordance with SOP SA-AN-041: *Reagent and Standard Materials Procedures.* Certificates of analysis or purity must be received with all purchased standards, and scanned and attached to the standard in TALS.

Refer to the appropriate SOP Attachment, as listed in Section 1, for the method-specific standards associated with each analysis. Other standard concentrations may be used provided they support the reporting limit and are fully documented in accordance with SOP SA-AN-041.

8.0 Sample Collection, Preservation, Shipment, and Storage

Refer to Attachment 2 for the method-specific sample collection, preservation, shipment, and storage information.

9.0 Quality Control

SOP SA-QA-017: *Evaluation of Batch QC Data* and the SOP Summary in Attachment 3 provide requirements for evaluating QC data. Refer to the appropriate SOP Attachment, as listed in Section 1, for any method-specific quality control information associated with each analysis.

9.1 Batch QC

A preparation/analysis batch consists of up to 20 environmental samples and the associated QC items analyzed together within a 24 hour period. Refer to the Table in Attachment 3 for a summary of the method-specific batch QC items.

If there is insufficient sample volume to perform the required matrix spike(s), an NCM must be initiated on all affected samples to denote this situation. Insufficient sample volume is defined as receiving less than a total of 20mL.

If insufficient sample volume is provided to perform the Sample duplicate (SD) or matrix spike/ matrix spike duplicate (MS/MSD), the Laboratory control sample (LCS) must be prepared in duplicate (LCS/LCSD). An NCM must be initiated on all samples within the batch to denote this situation.

Note: Unless the client has specified which sample to use as the matrix spike, the matrix spike must be selected at random from the samples in the batch. Field QC (e.g., equipment blanks, trip blanks, and field blanks) must not be used for MS/MSD unless specifically requested to do so by the client or unless there is insufficient sample available for performing MS/MSD using an actual field sample.

MRL LCS for DW

The EPA Manual for the Certification of Laboratories Analyzing Drinking Water requires a Laboratory fortified blank (LFB) at the MRL to be performed each day. Therefore, if analyzing drinking water samples, a Laboratory Control Sample (LCS) at the Reporting Limit (RL) must also be included in the required batch QC.

9.2 Instrument QC

9.2.1 Initial Calibration (ICAL)

The instrument must be calibrated in accordance with SOP SA-QA-016: *Evaluation of Calibration Curves.* This SOP provides requirements for establishing the calibration curve and gives the applicable formulas.

Instrument calibration is performed by analyzing a series of known standards. The calibration curve must consist of a minimum of 3 standards and a blank. The lowest level calibration standard must be at or below the reporting limit, and the remaining standards will define the working range of the analytical system.

The regression coefficient (r^2) of the regression curve must be greater than or equal to 0.995 for the initial calibration curve to be acceptable.

Readback Criteria : Each point on the curve must be within +/- 10% of true value.

9.2.2 Second Source Initial Calibration Verification (ICV)

The calibration curve must be verified initially – prior to any sample analyses – in accordance with SOP SA-QA-016 with a standard obtained from a second source.

The ICV must be within 10% to be acceptable.

9.2.3 Initial Calibration Blank (ICB) / Continuing Calibration Blank (CCB)/ Method Blank (MB)

The instrument must be shown to be free from contamination by the analysis of calibration blanks. Initial calibration blanks are analyzed at the beginning of each analysis run. Continuing calibration blanks are analyzed following each CCV.

SM3500-Fe B, SM3500 Fe-D SM3500-Cr B: Blanks must be < MDL
Other methods: Blanks must be < ½ RL.

9.2.4 Continuing Calibration Verification (CCV)
Unless noted elsewhere in this SOP, the initial calibration curve must be verified every 10 analyses and at the end of the analysis run with a mid-level standard.

The CCV must be within 10% to be acceptable.

9.2.5 Linear Calibration Range / Linear Dynamic Range
The linear calibration range (LCR), also known as the Linear Dynamic Range (LDR), must be determined initially for the following methods:

SM3500-Fe B
SM3500-Cr B
SM4500-NH_3 G
SM4500-P F
SM4500-Cl^- E
EPA 350.1
EPA 365.1

The initial demonstration of linearity uses as many standards as necessary to ensure the curve is linear. The standards should cover the low and high ends of the calibration range. Each standard must be within +/- 10% of the true value.

The LCR/LDR must be verified every 6 months for the following methods:
EPA 350.1
EPA 365.1

The continued demonstration of linearity consists of a minimum of 3 standards and a blank. For the linearity to be verified, the standards must be within +/-10% of the initial value to be acceptable. If this criterion is not met, the initial demonstration of linearity must be performed.

Note: This study is not meant to extend the linear range of the calibration. If an analyte is measured at a concentration greater than the highest calibration standard, the sample must be analyzed at a dilution to bring the target analyte into the range of the initial calibration.

9.3 Corrective Action for Out-of-Control Data
When the quality control parameters do not meet the criteria set forth in this SOP, corrective action must be taken in accordance with SOP SA-QA-005: *Preventive and Corrective Action Procedure* and the QC Summary Table in Attachment 3. SOP SA-QA-005 provides contingencies for out-of-control data and gives guidance for exceptionally permitting departures from approved policies and procedures. Nonconformance Memos must be initiated to document all instances where QC criteria are not met and all departures from approved policies and procedures.

10.0 Procedure

10.1 Sample Preparation

Remove the samples or extracts from the refrigerator and allow them to come to room temperature.

Soil samples must be homogenized prior to preparation in accordance with SOP SA-QA-015: *Compositing, Homogenization, and Segregation of Samples*. Note: If a sample or extract is filtered, the associated QC must also be filtered.

The sample preparation procedures are summarized below. Refer to appropriate SOP Attachment for the method-specific procedures.

Analyte	Aqueous Prep	Soil Prep
Ammonia	Distillation* (EPA 350.1 / SM4500-NH_3 B) Undistilled (No Prep)*	Soil Leachate
Chloride	No Prep	Soil Leachate
Total Chlorine	EPA 5050 (SOP SA-GE-010)	EPA 5050 (SOP SA-GE-010)
Ferrous Iron (Ferric Iron calc)	Filter	
Hexavalent Chromium (Trivalent Chromium calc)	Filter**	N/A
Ortho-Phosphate	Filter **	Soil Leachate
Sulfate	No Prep	Soil Leachate
Total Sulfur	EPA 5050 (SOP SA-GE-010)	EPA 5050 (SOP SA-GE-010)
BTU	ASTM D270-87	ASTM D240-87

*Ammonia samples are distilled upon client request.
** Samples should be field filtered.

10.2 QC Sample Preparation

Refer to appropriate SOP Attachment, as listed in Section 1, for the method-specific QC sample preparation instruction associated with each procedure.

10.3 Analysis

10.3.1 Instrument Operating Conditions

The instrument conditions listed in this SOP are provided for guidance purposes. The actual conditions used by the laboratory may be slightly different from those listed here and must be documented in the instrument maintenance log, data system, and/or run log.

Instrument maintenance must be performed in accordance with Attachment 4 of this SOP.

Data System
Programmable instrument parameters include:

Volume of sample (maximum of 125uL)
Wavelength
Type and order of reagent(s) addition
Background absorbance
Time of sample/reagent mixing
Timing of absorbance readings
Dilutions
Reagents lot numbers/expiration dates

QC checks can be programmed into the methods as needed, including initial and continuing control standards, blanks, and upper and lower limits on absorbance. If samples or standards exceed these control limits, the data are flagged.

Operation
The instrument utilizes the following process:

- Sample is dispensed into the cuvettes according to the test method (maximum sample volume is 125uL)
- The reagents are added to the sample and mixed.
- The sample is incubated.
- The sample absorbance is measured (if absorbance exceeds calibration range, sample is diluted as defined in the test method and reanalyzed. If the dilution exceeds the maximum range, the data are flagged and the analyst must prepare dilution for sample).

10.3.2 Initial and Continuing Calibration

The instrument is calibrated using the standards and criteria described in the appropriate SOP Attachment, as listed in Section 1. Once the calibration has been established and verified with an ICV in accordance with Section 9.2.2, sample analysis may proceed.

Verify the calibration curve with a continuing calibration verification using the standards and criteria described given in Section 9.2.4 and the appropriate SOP Attachment, as listed in Section 1.

10.3.3 Sample Analysis

Remove the samples or extracts from the refrigerator and allow them to come to room temperature.

Samples are loaded into racks that hold 14 samples each. The autosampler holds up to 6 racks of 14 samples. The racks can be fitted to hold sample containers from 0.5mL up to 10mL. Two separate wash stations are used to minimize sampler carryover. The probe is flow-through and externally rinsed.

The sample/extract must be analyzed using the same volume used for the calibration standards. The default procedure is to include QC items (method blank, LCS, MS/MSD, and SD) in determining the maximum number of samples in the analysis.

10.3.4 Example Analytical Sequence

Refer to the appropriate SOP Attachment, as listed in Section 1, for any changes to the sequence listed below.

Description	Comments
Blank	
Initial Calibration	
ICV	Second Source
ICB	
Samples & Batch QC Items	Up to 10 analyses. Not to exceed 2 hours.
CCV	
CCB	
Samples & Batch QC Items	Up to 10 analyses. Not to exceed 2 hours.
CCV	
CCB	

11.0 Calculations / Data Reduction

11.1 Data Reduction

Data must be evaluated in accordance with SOP SA-QA-002: *Data Review and Reporting*.

11.1.1 MS/MSD Evaluation

If the concentration of a target analyte in the un-spiked (native) sample is more than four times the theoretical concentration of the matrix spike, the recovery is not reported and the data is flagged.

11.1.2 Historical Data

Many of the laboratory's clients submit samples for repeat monitoring purposes. Prior to analysis, verify TALS Worksheet Notes and/or use the TALS Historical Data Tracker Feature to determine if historical data is available for review.

11.1.3 Chemical Relationships

When available, the following chemical relationships must be evaluated for each sample. If these relationships are not met the Department Manager must be contacted immediately.

- Total Results ≥ Dissolved Results
- TKN ≥ Ammonia
- Total Phosphorus ≥ Ortho-phosphate
- TDS ≥ Individual Anions
- Ferrous Iron ≤ Total Iron

11.1.4 Drinking Water Compliance Evaluation

Public water suppliers (PWS) are governed by EPA-specified Maximum Contaminant Levels (MCL) above which indicates noncompliance. The MCLs associated with this procedure are given in Attachment 5. Notify the PM immediately via a Nonconformance Memo if any sample contains detection above these levels.

11.2 Calculations

11.2.1 The calculations associated with batch QC determinations are given in SOP SA-QA-017. Applicable calculations include accuracy (% recovery) and precision (%RPD).

11.2.2 The calculations associated with initial and continuing calibrations and are given in SOP SA-QA-016. Applicable calculations include determination for: calibration factor, standard deviation, relative response factor, and relative standard deviation.

11.2.3 The calculation to determine final concentration is given as follows:

$$FinalConcentration = CONC_{Sample} \otimes \frac{F}{I \times dw} \otimes D$$

Where:

$CONC_{Sample}$= Concentration of the sample
F = Final volume/weight
I = Initial volume/weight
dw = % Solids decimal equivalent
D = Dilution factor

Note: All dry weight corrections are performed automatically in TALS.

12.0 Method Performance

12.1 Reporting Limit Verification (RLV)

At a minimum, RLVs must be performed initially upon method set-up in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits*.

For analytes and methods certified by DOD ELAP, RLVs must be performed quarterly thereafter.

12.2 Method Detection Limit (MDL) Study

The method detection limits (MDL) is defined as the minimum measure concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from the method blank results. MDLs reflect a calculated (statistical) value determined under ideal laboratory conditions in a clean matrix and may not be achievable in all environmental matrices. The current MDLs associated with this procedure are given in the Method Limit Group (MLG) in TALS.

At a minimum, MDL Studies must be performed initially upon method set-up in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits*.

Note: MDL Studies are not required for non-routine analytes provided results are not reported below the RL (i.e., MDL equals RL in TALS).

12.3 Method Detection Limit Verification (MDLV)

At a minimum, MDLVs must be performed initially upon method set-up in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits*.

12.4 QC Limit Generation, Control Charting, and Trend Analysis

The control limits for the batch QC items (LCS, MS/MSD, SD) for this procedure are specified in the reference method and cannot be broadened; therefore, the laboratory defaults to the method-defined limits and does not utilize in-house or laboratory-derived limits for the evaluation of batch QC items.

Although the laboratory must default to the method-defined QC limits, control charting is a useful tool and is performed to assess analyte recoveries over time to evaluate trends. Control charting must be performed periodically (at a minimum annually) in accordance with SOP SA-QA-017: *Evaluation of Batch QC Data.*

12.5 Demonstrations of Capability

Initial and continuing demonstration of capability must be performed in accordance with SOP SA-QA-006*: Training Procedures.*

Prior to performing this procedure unsupervised, each new analyst who performs this analysis must demonstrate proficiency per method/analyte combination by successful completion of an initial demonstration of capability. The IDOC is performed by the analysis of 4 consecutive LCSs that meet the method criteria for accuracy and precision. The IDOC must be documented and routed to the QA Department for filing.

Annual continuing demonstrations of capability (CDOCs) are also required per analyst per method/analyte combination. The CDOC requirement may be met by the consecutive analysis of four LCS all in the same batch, by the analysis of four LCS analyzed in four consecutive batches (in different batches on different days), via acceptable results on a PT study, or analysis of client samples with statistically indistinguishable results when compared to another certified analyst. The CDOC must be documented and routed to the QA Department for filing.

12.4 Training Requirements

All training must be performed and documented in accordance with SOP SA-QA-006: *Training Procedures*.

Note: The SOPs listed in the Reference/Cross-Reference Section are applicable to this procedure. All employees performing this procedure must also be trained on these SOPs.

13.0 Pollution Control

It is Eurofins Savannah's policy to evaluate each method and look for opportunities to minimize waste generated (e.g., examining recycling options, ordering chemicals based on quantity needed, preparing reagents based on anticipated usage and reagent stability, etc.). Employees must abide by the policies in Section 13 of the Environmental Health and Safety Manual.

This procedure has been evaluated for opportunities to minimize the waste generated. Where reasonably feasible, pollution control procedures have been incorporated.

14.0 Waste Management

Waste management practices must be conducted consistent with all applicable federal, state, and local rules and regulations. All waste (i.e., excess reagents, samples, and method process wastes) must be disposed of in accordance with Section 9 of the Eurofins Savannah Addendum to the EHSM. Waste description rules and land disposal restrictions must be followed.

14.1 Waste Streams Produced by the Method

The following waste streams are produced when this method is carried out:

- Excess aqueous samples – Dispose according to characterization by the disposal program. Neutralize non-hazardous samples before disposal into drain/sewer. Transfer hazardous samples to the waste department for disposal.

- Excess soil and solid samples – Dispose according to characterization by the disposal program. Transfer hazardous and non-hazardous samples to the yardbox in the waste storage area for disposal via incineration. Samples classified as PCB or Foreign Soil hazardous must be transferred to the waste coordinator for drumming.

- Non-hazardous acidic and alkaline wastewater and samples must be neutralized before disposal into the sewer system.

16.0 Method Modifications and Clarifications

16.1 Many of the reference methods were written specifically for drinking water and source water samples; however, the laboratory may perform other types of water samples using these procedures. These procedures may be modified to analyze other matrices (e.g., wipe samples) based on the needs of the client. This will need to be arranged by the Project Manager at the initiation of the project. Wipe, waste, and tissue matrices are non-routine, and the laboratory is not currently NELAC certified for these matrices. The laboratory uses its routine soil RLs and MDLs (converted for initial and final volumes, etc.), and soil QC limits to evaluate wipe, waste, and tissue samples. Soil DOCs can be used to satisfy analyst demonstrations of capability for these types of non-routine matrices. Ottawa sand is used as the blank matrix for tissue samples unless a “true” tissue matrix is required by the project.

16.2 The EPA Manual for the Certification of Laboratories Analyzing Drinking Water requires a LFB at the MRL to be performed each day. The laboratory meets this requirement by preparing an LCS at the RL in each batch of drinking water samples.

16.3 Refer to appropriate SOP Attachment, as listed in Section 1, for any method-specific modifications and/or clarifications associated with each procedure.

16.4 The default procedure for the ammonia analysis is to analyze samples undistilled. An equivalency study has been conducted using a variety of sample matrices and shows similar results were obtained for undistilled versus distilled samples. Distillation for ammonia samples can be performed upon client request.

17.0 Attachments

The following Tables, Diagrams, and/or Validation Data are included as Attachments:

Attachment 1a: SOP Summary – Ammonia
Attachment 1b: SOP Summary – Chloride and Total Chlorine
Attachment 1c: SOP Summary – Ferrous Iron and Ferric Iron
Attachment 1d: SOP Summary – Hexavalent Chromium and Trivalent Chromium
Attachment 1e: SOP Summary – Ortho-phosphate
Attachment 1f: SOP Summary – Sulfate, Total Sulfur, and BTU
Attachment 2: Sample Collection, Preservation, and Holding Time Table
Attachment 3a: Batch QC Frequency
Attachment 3b: QC Summary
Attachment 4: Instrument Maintenance and Troubleshooting
Attachment 5: Maximum Contaminant Levels (MCL) Table
Attachment 6: Glassware Cleaning Procedures

Attachment 1a
SOP Summary
Ammonia

1.0 Summary

Ammonia reacts with hypochlorite and alkaline phenol to form indophenol blue. The blue color produced is intensified with sodium nitroprusside and measured at 660nm.

2.0 Interferences

Extreme sample pH values may interfere. Proper sample preservation and adjustment just prior to analysis should alleviate this problem. Turbidity and color in samples must be filtered and/or diluted prior to analysis. Residual chlorine should be removed at the time of sampling by the addition of sodium thiosulfate.

3.0 Reagents and Standards

3.1 Purchased Reagents

Sodium Thiosulfate ($Na_2S_2O_3 \cdot 5H_2O$) Dechlorination Reagent – reagent grade

Sulfuric Acid (H_2SO_4) – concentrated, reagent grade
Storage: Area with acid resistant floors. Store away from direct sunlight, heat, and water.

Sodium Hydroxide (NaOH) – pellets, reagent grade
Storage: Isolate from moisture and heat sources.

Potassium Chloride (KCl) – reagent grade

Phenol – solution must be $\geq$89% pure
Storage: Isolate from heat or ignition sources.

Sodium Tetraborate ($Na_2B_4O_7$) – reagent grade

Bleach/Sodium Hypochlorite – must contain 6.15% sodium hypochlorite (NaOCl)
Storage: Protect from heat and light.
Expiration: Unopened: 1 year; Opened: 6 months

Disodium Ethylenediamine Tetraacetate (EDTA) – reagent grade

Sodium Nitroprusside ($Na_2(NO)Fe(CN)_5 \cdot 2H_2O$) – reagent grade
Storage: Away from moisture and incompatibles

3.2 Prepared Reagents

Sodium Phenate Solution
Dissolve 9.3mL liquid (≥89%) phenol in 50mL ammonia free water, slowly add 3.2g NaOH and mix thoroughly and dilute to 100mL with DI Water. **CAUTION**: Wear gloves and eye protection when preparing this solution.
Expiration: Daily

Sodium Hypochlorite Solution
Dilute 25mL of 5.25% NaOCl with 50mL DI Water. (Note: If "concentrated" bleach is used (8.25% NaOCl), measure 16mL and dilute to 50mL with DI Water.)
Expiration: Daily

EDTA Buffer
Dissolve 50g of disodium ethylenediamine tetraacetate and 5.5g of NaOH in 1000mL of DI water.
Expiration: 1 year

Sodium Nitroprusside Solution
Dissolve 0.5g of $Na_2(NO)FE(CN)_5.2H_2O$ in 1000mL of DI Water.
Expiration: 1 year

5% Sulfuric Acid Solution
Add 50mL of concentrated sulfuric acid to a 1L volumetric flask containing 500mL DI water. Bring to volume with DI water.

Sulfuric Acid Solution (0.01M) – NH3_Diluent
Add 2.08mL of concentrated sulfuric acid to 1.0 gallon of water (0.56mL of concentrated H2SO4 per liter of water). The pH of this solution is 2.0. Verify the pH before use.
Expiration: 1 year

2N Sodium Hydroxide Solution
In a 1L volumetric flask add 500mL of DI water. Add 80 grams of sodium hydroxide pellets and let dissolve. Bring to volume with DI water after the pellets have dissolved. Mix well.
Expiration: 1 year

Sodium Hydroxide Solution (15N)
Add 250mL DI Water to a 500mL volumetric flask. Add a stir bar and place on stir plate. In small increments and with constant stirring, slowly add 300g NaOH to the flask. Allow to cool and dilute to volume with DI water. Transfer to a labeled storage container.
Expiration: 1 year

Potassium Chloride (1M)
Dilute 148g of potassium chloride to with 1800mL DI Water. Add 1.12mL concentrated sulfuric acid. Dilute to 2000mL and mix thoroughly.
Expiration: 1 year

O-Cresolphthalein Indicator Solution 0.2% w/v alcoholic solution.
Expiration: Manufacturer's expiration date

MicroDist Trapping Solution
Add 3.3mL of concentrated sulfuric acid to 1.0L of water.
Expiration: 1 year

Borate Buffer (MicroDist)
Add 5.0g of sodium borate decahydrate and 22g sodium hydroxide to 600mL of DI Water in a 1L volumetric flask. Stir to dissolve then add 10mL o-cresolphthalein indicator solution. Dilute to mark with DI Water. Buffer should be a deep purple color.
Expiration: 1 year

3.3 Standards

Ammonia Stock Standard (100mg/L) Purchased
Expiration: Manufacturer's expiration date

Ammonia Calibration Standards
Prepare calibration standards in 0.01M Sulfuric Acid (NH3 Diluent) according to the following table.

Standard Level	Parent Standard	Volume Intermediate (mL)	Final Volume (mL)	Final Concentration (mg/L)
1	Ammonia Stock Standard	2.0	100	2.0
2 (LCS)	Ammonia Stock Standard	10	1000	1.0
3	Ammonia Stock Standard	0.50	100	0.50
4	Ammonia Stock Standard	0.25	100	0.25
5	Ammonia Stock Standard	0.10	100	0.10
6	Cal 2	5.0	100	0.050
7	Cal 2	2.5	100	0.025

Initial Calibration Verification (ICV) – 1.0mg/L standard from NCL Labs. Adjust to pH 2 with a weak solution of H2SO4.
Expiration: manufacturer's date (1 month if no date given)

4.0 Sample Preparation

4.1 Aqueous Samples
Aqueous samples are routinely analyzed with no sample preparation. The samples can be distilled upon request.

NOTE: All compliance samples originating from West Virginia or South Carolina must be distilled prior to analysis.

Residual Chlorine Check (for Ammonia analyses only)
For each sample,
- Place a piece of starch-iodide paper in a disposable medicine cup.
- Pour a few drops of sample into the medicine cup and note the color change of the paper.
- If the paper turns blue or black, residual chlorine is present. Initiate a Nonconformance Memo and dechlorinate the sample with sodium thiosulfate.

pH Verification (for Ammonia analyses only)
For each sample,
- Create a preservation batch in LIMS (preserv_chk)
- Place a piece of pH paper in a disposable medicine cup. Use narrow range 1.0-2.5 pH paper.
- Pour a few drops of sample into the medicine cup and note the color change of the pH paper.
- If the pH is greater than 2, initiate a Nonconformance Memo. Adjust the sample pH to 2 or less, targeting a value near pH 2, using sulfuric acid. The volume of sulfuric acid must not exceed 1% of the volume of the container or sample; e.g., no more than 2.5mL of sulfuric acid per 250mL container or sample.

Note: To avoid cross-contamination, use a separate medicine cup, pH strip, and residual chlorine strip per sample. Do not dip the strip into the sample container.

Prepare QC samples in the same manner as field samples as follows:
- Laboratory Control Sample (LCS) – Prepared in same manner as Cal Level 2.
- Low-Level Laboratory Control Sample- (LLCS) (Drinking Water only) – Performed at the RL (0.25mg/L) for routine DW samples. Performed at 0.05mg/L for FP
- Matrix Spike / Matrix Spike Duplicate (MS/MSD) – Add 0.1mL of the 100mg/L Ammonia Stock Standard to 10mL of the sample selected for MS/MSD.

  Note: SM4500-NH3 G recommends the MS/MSD spike concentration to be varied periodically.

4.1.1 Ammonia Micro-Distillation Preparation

Create a Distill_Ammonia batch in LIMS.

Set controller to 120°C and turn on the heater block to warm up (~40 min). Verify the temperature of the micro-distillation apparatus with an IR gun. The temperature must be within 115-125°C. Record the corrected and uncorrected temperature in the Batch Data Types in TALS.

Determine the number of collector tubes needed and align with “M” end in the up position by placing them into a collector tube rack.

Label and fill each collector tube with 1mL of trapping solution (0.016M Sulfuric Acid). At the end of the distillation, once diluted to 6mL final volume, the final concentration will be 0.003M Sulfuric Acid.

Place the same number of sample tubes into the sample tube rack.

Label each tube and place 6mL of sample into each sample tube.

Add 1mL of 0.55M Borate Buffer to each tube. Ensure the sample plus buffer remains purple (pH >9.8). If purple color fades when the buffer is added, add additional NaOH Solution to bring the pH up until the purple color returns.

Immediately push the “D” end of the collector tube over the open end of the sample tube to start the seal.

Place the tube assembly in the press by putting the sample tube through the hole in the base.

Before pressing, place one hand at the breakaway point located on the collector tube to stabilize the assembly.

Apply pressure to the assembly with a smooth motion until the stop ring on the sample tube hits the “D” end of the collector tube.

Once complete, put on heat resistant gloves and add the tube assemblies to the pre-heated block by placing the sample tube and “D” end of the collector tube into the block.

Set the timer for 30 minutes. Document the start time in the LIMs batch.

Once time is up remove the assemblies from the block one at a time and immediately remove the sample tube from the collector tube and invert so the D side is facing up. Note: this should be done within 4 seconds to prevent “suck-back” of the sample.

Document the end time, uncorrected temperature and corrected temperature in the batch information.

Once all of the tubes have been removed and disassembled, seal with Parafilm at the “I” end of the tube and allow the tubes to cool for 10 minutes.

Hold the tube horizontally and roll the tube with your fingers to gather the droplets that are stuck to the walls. The tube can be flicked with your finger as well.

With the “D” end still up, grasp the tube and break it at the breakaway point by pulling the “D” end towards your body and twisting the tube. Discard the “D” end of the tube.

Perform a pH check of samples to ensure they are still at a pH of 2. If not, adjust with Sulfuric Acid prior to diluting up to 6mLs. Use narrow range pH paper with a range of 1-2.5 for this check.

Dilute the distillate up to the 6 mL mark with NH3 Diluent and cover the tube with Parafilm until ready for analysis.

4.2 Soil Samples

- Weigh approximately 20g of sample into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 100mL of 2M potassium chloride to each sample container and place in the tumbler.
- Rotate for 30-45 minutes. Remove the containers from the extractor and allow the leachates to settle.
- Filter the extract using a syringe filter with a 0.45um pore size filter and analyze the extracts as liquid samples.

Prepare QC samples in the same manner as field samples as follows:

- Method Blank – Weigh approximately 20g of Teflon chips into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g.
- Laboratory Control Sample – Weigh approximately 20g of Teflon chips into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 1mL of 100mg/L Ammonia Intermediate Standard to the extraction bottle. Spike soil prior to adding 99ml of 2M potassium chloride.
- MS/MSD – Weigh additional 20g aliquots of one of the samples for the MS/MSD. Add 1mL of 100mg/L Ammonia Intermediate Standard Ammonia Matrix Spike Solution to the sample. Spike soil prior to adding 99ml of 2M potassium chloride.

5.0 Method-Specific QC Requirements

5.1 Linear Calibration Range
EPA 350.1 – Performed initially; verified every 6 months.
SM4500-NH_3 G – Performed initially.

5.2 Method Detection Limit Studies
EPA 350.1 – Requires MDL Studies every 6 months.
SM4500-NH_3 G – Requires MDL Study to be analyzed over 3-5 days.

6.0 Method-Specific Modifications and/or Clarifications

The ammonia distillation sample volumes have been adjusted to compensate for current lab restrictions of glassware and volume of sample submitted. All reagent volumes have been adjusted accordingly.

The reference methods state to adjust sample pH with 1N NaOH. The sample is preserved with H_2SO_4 to a pH of <2. To adjust the pH with such a weak solution would require adding >5% volume and therefore diluting the sample. As such, the laboratory uses 15N NaOH to adjust the sample pH.

The default procedure for the ammonia analysis is to analyze samples undistilled. An equivalency study has been conducted using a variety of sample matrices and shows similar results were obtained for undistilled versus distilled samples. Distillation for ammonia samples can be performed upon client request.

Attachment 1b
SOP Summary
Chloride & Total Chlorine

1.0 Summary

Chloride reacts with mercuric thiocyanate forming a mercuric chloride complex. Released thiocyanate reacts with iron (III) forming a red ferric thiocyanate complex the color produced, measured at 480nm, is proportional to the chloride concentration.

Refer to SOP SA-GE-010 for information on the preparation procedures for Total Chlorine. The attached Work Instruction provides the procedural and calculation information.

2.0 Interferences

Highly colored samples can positively interfere. Turbid samples should be filtered.

3.0 Reagents and Standards

3.1 Purchased Reagents

Mercuric Thiocyanate [$Hg(SCN)_2$] – reagent grade
Storage: Protected from light.

Methanol – HPLC or P&T grade
Storage: Protect from heat, sparks, and flame in a flammable storage area.

Ferric Nitrate [$Fe(NO_3)_3.9H_2O$] – reagent grade
Storage: Away from sources of heat and moisture. Avoid storage on wooden floors.
Expiration: 1 year

Nitric Acid, concentrated – A.C.S. grade
Storage: acid resistant floors and good drainage; away from sunlight, heat, and water.

3.2 Prepared Reagents

Ferric Nitrate Solution (20.2%) – Dissolve 202g $Fe(NO_3)_3.9H_2O$ into 500mL reagent water. Carefully add 44.4mL of concentrated nitric acid. Mix and dilute to 1L with reagent water. Store in an amber bottle away from light.
Expiration: 1 Year

Mercuric Thiocyanate Solution (Saturated) – Dissolve 4.16g $Hg(SCN)_2$ into 500mL of methanol. Dilute to 1L with methanol, mix, and filter. Dispose if reagent becomes discolored or cloudy.
Storage: Protected from light.
Expiration: 1 year

Color Reagent – Add 75mL of Mercuric Thiocyanate Solution to 75mL Ferric Nitrate Solution. Mix and dilute to 500mL with reagent water. Dispose if reagent becomes discolored or cloudy.
Storage: Tightly closed-light resistant container. Protect from light.
Expiration: 3 months

3.3 Standards

Sodium Chloride (NaCl) – reagent grade

Chloride Calibration Stock (1000mg/L) – Purchased from Inorganic Ventures.
Expiration: manufacturer's expiration date or one year, whichever is shorter.

Chloride Calibration Standards

Standard Level	TALS Reagent Name	Parent Standard	Aliquot (mL)	Final Volume (mL)	Final Concentration (mg/L)
1	Cl CAL10	Cl Cal Stk	0.1	100	1
2	Cl CAL6	Cl Cal Stk	1.0	100	10
3	Cl CAL5	Cl Cal Stk	2.0	100	20
4	Cl CAL4	Cl Cal Stk	4.0	100	40
5	Cl CAL12	Cl Cal Stk	5.0	100	50

Dilute to volume in reagent water.

Chloride Laboratory Control Sample (LCS) (25mg/L) – Add 6.25mL Chloride Calibration Stock to a 250mL volumetric. Dilute to volume with reagent water. This standard is also used as the CCV.

Chloride ICV Stock (1000mg/L) – Purchased from NSI.
Expiration: manufacturer's expiration date or one year, whichever is shorter.

Chloride ICV (25mg/L) – Add 2.5mL of Chloride ICV Stock to a 100mL volumetric flask. Dilute to volume with reagent water.

4.0 Sample Preparation

4.1 Aqueous Samples
Aqueous samples are routinely analyzed with no sample preparation.

Prepare QC samples in the same manner as field samples as follows:

- Laboratory Control Sample (LCS) – prepared as described above
- Low-Level Laboratory Control Sample (LLCS) (Drinking Water only) – Lowest level standard of the initial calibration
- MS/MSD – Add 0.25mL of Chloride Calibration Stock to 10mL of the sample selected for MS/MSD. Note: SM4500-Cl^- E recommends the MS/MSD spike concentration to be varied periodically.
- Sample Duplicate (SD) – Prepare an additional aliquot of the chosen sample.

4.2 Soil Samples

- Create a preparation batch in LIMS
- Weigh approximately 5g of sample into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 100mL of reagent water to each sample container and place in the tumbler.
- Rotate for 15minutes.
- Remove the containers from the extractor and allow the leachates to settle. Filter the extract using a chloride-free 25mm PTFE syringe filter with a 0.20µm pore size and analyze the extracts as liquid samples.

Prepare QC samples in the same manner as field samples as follows:

- Method Blank – Weigh approximately 5g of Teflon Chips into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g.
- Laboratory Control Sample – Weigh approximately 5g of Teflon Chips into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 2.5mL of the Chloride Cal Stock (1000mg/L) Solution and 97.5mL of DI water.
- MS/MSD – Weigh 2 additional 5g aliquots of one of the samples for the MS/MSD. Add 2.5mL of the Chloride Cal Stock (1000mg/L) Solution and 97.5mL of DI water to each bottle.

5.0 Method-Specific QC Requirements

5.1 Linear Calibration Range
SM4500-Cl^- E – Performed initially.

5.2 Method Detection Limit Studies
SM4500-Cl^- E – Requires MDL Study to be analyzed over 3-5 days.

6.0 Method-Specific Modifications and/or Clarifications

6.1 The SM4500-Cl^- E reference method specifies to use 21mL nitric acid to prepare the ferric nitrate solution. The EPA 325.2 and EPA 9251 reference methods specify 31.5mL. The laboratory utilizes 44.4mL as outlined in the Konelab application notes.

6.2 The SM4500-Cl^- E reference method includes the addition of polyoxyethylene 23 lauryl ether to the color reagent. This is not required by the other methods and has been omitted from the laboratory's procedure.

Calculation of Total Chlorine / Total Halogen

Method: SW-846 5050 in conjunction with SW-846 9056A or 9251

Summary of Procedure:

Total chlorine / total halogens (as total chlorine) in a sample is determined by oxygen bomb combustion using SOP SA-GE-010: *Bomb Preparation*. The sample is oxidized by electrical ignition in a bomb containing oxygen under pressure. Under these conditions, chlorine is converted to inorganic chloride and recovered in the DI water bomb washings. The chloride is quantitated using either ion chromatography (SOP SA-GE-115: *Ion Chromatography*) or Konelab (SOP SA-GE-001: *Measurement of Analytes using the Konelab Analyzer*).

Two fundamental conditions must apply before a sample can be considered to have combusted:

1. Some part of the sample must be heated to its ignition temperature to start the combustion. Then in burning, the sample must liberate sufficient heat to support its own combustion.
2. The combustion must produce enough turbulence within the bomb to bring oxygen into the fuel cup for burning the sample completely.

Calculation:

The calculation of Total Chlorine is performed by the LIMS system.

$$Total\ Halogen, mg/kg\ dw = \frac{A \times B \times C}{D \times E}$$

Total Chlorine / Total Halogens (as Total Chlorine)

where

A = chloride concentration determined by IC or Konelab in mg/L
B = final volume of bomb washings in liters (0.10L)
C = 1000g/kg conversion factor.
D = sample weight in grams
E = decimal fraction of the percent solids

**NOTE-- Oil matrices will not have a percent solids, therefore the E variable is dropped from the calculation, and the total halogen is reported as mg/kg as is.

Quality Control:

This procedure is a calculation only; therefore, there are no QC items associated. Formal detection limit studies, as described in 40CFR Part 136B and SOP SA-QA-07: *Determination of Detection Limits,* are not required.

Formal demonstrations of capability (DOCs) are described in section 12.2 of SOP SA-GE-010.

Attachment 1c
SOP Summary
Ferrous Iron and Ferric Iron

1.0 Summary

Ferrous iron is determined by reaction with phenanthroline in acid solution producing an orange color with a maximum absorbance of 510nm.

Ferric iron is performed via the calculation below. The Total Iron result is obtained via ICP and/or ICP/MS analysis in accordance with SOP SA-ME-070 or SA-ME-074.

Ferric Iron = Total Iron – Ferrous Iron

2.0 Interferences

The reaction of ferrous iron with 1,10-phenanthroline is free from common interferences. Long storage times or exposure of samples to light must be avoided. Protect from light and analyze as soon as possible.

3.0 Standards and Reagents

3.1 Purchased Reagents

Hydrochloric Acid (HCl) – concentrated, A.C.S. grade
Storage: Acid resistant floors and good drainage. Store away from sunlight, heat and water.

Glacial Acetic Acid (CH_3COOH) – concentrated, A.C.S. grade
Storage: Acid resistant floors and good drainage. Protect from freezing. Store away from sunlight, heat, and ignition sources.

Ammonium Acetate ($NH_4C_2H_3O_2$) – reagent grade

1,10-phenanthroline monohydrate ($C_{12}H_8N_2 \cdot H_2O$) – reagent grade

3.2 Prepared Reagents

Hydrochloric Acid (1:1) – Slowly add 500mL concentrated HCl to about 400mL DI Water in a 1-L volumetric flask, cool and dilute to volume with DI water. This solution must be prepared in a hood.
Expiration: parent's expiration date or within 1 year of preparation, whichever comes first

Ammonium Acetate Buffer Solution – Dissolve 150g $NH_4C_2H_3O_2$ into 150mL DI Water. Add 700mL concentrated glacial acetic acid. Note: Because $NH_4C_2H_3O_2$ contains a significant amount of iron, new reference standards must be made with each buffer preparation.
Expiration: 5 years (not to exceed expiration of parent reagents).

Phenanthroline Solution (Color Reagent) – Dissolve 100mg $C_{12}H_8N_2 \cdot H_2O$ into 100mL of reagent water. Add 2 drops of concentrated HCl. Discard this solution if it darkens.
Expiration 1 year.

Diluent – 30ml of reagent water acidified to pH <2.0 with 1:1 HCl. For use in Kone instrument.

3.3 Standards

Ferrous Ammonium Sulfate [$Fe(NH_4)_2(SO_4)_2 \cdot 6H_2O$] – reagent grade; Note: The laboratory utilizes two independent lots of ferrous ammonium sulfate. One lot (Mallinckrodt) is utilized as the primary source for calibration standards, laboratory control samples, and matrix spikes. The second lot (Hach) is utilized as the secondary source for the initial calibration verification (ICV).

Ferrous Iron Solution (1000mg/L) – Dissolve 0.7022g $Fe(NH_4)_2(SO_4)_2 \cdot 6H_2O$ (primary source) into 50mL of reagent water in a 100mL volumetric flask. Acidify to pH <2 with 1:1 HCl and dilute to volume with reagent water.

Ferrous Iron Calibration Standards

Standard Level	TALS Reagent Name	Parent Standard	Aliquot (mL)	Final Volume (mL)	Final Concentration (mg/L)
1	FeCal7	1000mg/L	0.0050	100	0.050
2	FeCal6	1000mg/L	0.010	100	0.10
3	FeCal5	1000mg/L	0.030	100	0.30
4	FeCal4	1000mg/L	0.050	100	0.50
5	FeCal3	1000mg/L	0.10	100	1.0
6	FeCal2	1000mg/L	0.30	100	3.0
7	FeCal1	1000mg/L	0.50	100	5.0

Dilute to volume in reagent water.
Expiration: one month.

Ferrous Iron Matrix Spike Solution (40mg/L) – Dilute 4mL of the 1000mg/L Fe+2 Cal Stk to a final volume of 100mL with DI water.
Expiration: one month.

Ferrous Iron Laboratory Control Sample (2.0mg/L) – Dilute 5.0 mL of the 40mg/L matrix spike solution to a final volume of 100mL with DI water.
Expiration: one month.

Ferrous Iron ICV Stock Solution (1000mg/L) – Dissolve 0.7022g $Fe(NH_4)_2(SO_4)_2 \cdot 6H_2O$ (secondary source) into 50mL of reagent water in a 100mL volumetric flask. Acidify to pH <2 with 1:1 HCl and dilute to volume with reagent water.

Ferrous Iron Initial Calibration Verification (ICV) (3.0 mg/L) – Dilute 0.30mL of the 1000mg/L Fe+2 ICVSTK to a final volume of 100mL with DI water.
Expiration: one month.

4.0 Sample Preparation

4.1 Aqueous Samples

10mL of sample are filtered through a 0.45 micron filter prior to analysis. Add approximately 0.05mL (1 drop) of 1:1 HCl to adjust the sample to a pH 1.5–2.5. Use narrow range pH paper during adjustment to verify the proper pH is achieved.

Prepare QC samples in the same manner as field samples as follows:

- Continuing Calibration Verification- prepared as described above.
- Continuing Calibration Blank- reagent water acidified to a PH <2.0 with 1:1 HCl
- Method Blank- reagent water acidified to a PH <2.0 with 1:1 HCl
- Laboratory Control Sample – prepared as described above.
- Low-Level Laboratory Control Sample (Drinking Water only) – Lowest level standard of the initial calibration.
- Matrix Spike/Matrix Spike Duplicate – Add 0.50mL of Ferrous Iron Matrix Spike Solution to 10mL of the chosen sample
- .

4.2 Soil samples are not performed for this analysis.

5.0 Method-Specific QC Requirements

5.1 Linear Calibration Range required to be performed initially.

5.2 Reporting limit verification required for every batch. An RL check standard must be analyzed at the beginning of each sequence.

5.3 Analyze CCV immediately after ICAL (in addition to the ICV). Recovery must be within 5% of true value.

5.4 Any sample containing detection greater than 90% of the determined LDR must be diluted to until the raw result is less than 90% of the determined LDR.

6.0 Method-specific Modifications and/or Clarifications

6.1 The preparation of the Ferrous Iron Solution (1000mg/L) has been revised from the reference method to correspond to that outlined in the Konelab Application Notes.

Attachment 1d
SOP Summary
Hexavalent Chromium and Trivalent Chromium

1.0 Summary

The sample is acidified to pH 2 (+/-0.5) and 1,5-diphenylcarbazide (a color reagent) is added. The intensity of the purple color, measured at 540nm, is proportional to the concentration of hexavalent chromium present in the sample.

Trivalent Chromium is performed via the calculation below. The Total Chromium result is obtained via ICP and/or ICP/MS analysis in accordance with SOP SA-ME-070 or SA-ME-074.

Trivalent Chromium = Total Chromium – Hexavalent Chromium

2.0 Interferences

Iron in concentrations of greater than 1mg/L may produce a yellow color, but this is usually not significant when measured at 540nm. Hexavalent molybdenum and mercury salts react to form colored complexes with the color reagent, but the intensities of the colors produced are much lower than for chromium at the specified pH. Mercury and molybdenum concentrations of up to 200mg/L can be tolerated. Vanadium interferes more strongly, but concentrations of up to 10 times that of chromium can be tolerated.

All samples analyzed must be adjusted to a pH range of 1.5-2.5 with sulfuric acid prior to analysis to minimize interference and allow proper color development.

After acidification, soil digestates should be purged with helium to eliminate excess carbon dioxide gas. Bubble formation in the cuvettes can interfere with readings.

The recovery of soluble forms of hexavalent chromium may be low where the sample matrix contains substances that are readily oxidized by hexavalent chromium (a reducing matrix). The measurement pH and oxidation-reduction potential may provide information about the ability of hexavalent chromium to persist in the sample.

3.0 Standards and Reagents

3.1 Purchased Reagents

Phosphoric acid (H_3PO_4) – concentrated, A.C.S. grade
Storage: Acid resistant floors and good drainage; away from sunlight, heat and water.

Sulfuric Acid (H_2SO_4) – concentrated, A.C.S. grade
Storage: Acid resistant floors and good drainage; away from sunlight, heat, and water.

Acetone – concentrated, A.C.S. grade
Storage: Protect from heat, sparks, and flame in a flammable storage area.

1,5-diphenylcarbazide – reagent grade
Storage: Protect from light and store in desiccator.

3.2 Prepared Reagents

Sulfuric Acid (50% v/v) – Slowly add 50mL concentrated H_2SO_4 to about 40mL reagent water in a 100mL volumetric flask, cool and dilute to volume with reagent water. This solution must be prepared in a hood.

Color Reagent – Transfer 0.1250g of 1,5-diphenylcarbazide to 25mL volumetric flask. Add 10mL acetone; swirl to dissolve. Dilute to volume with acetone. Discard if reagent becomes discolored.
Storage: Store in the dark in a tightly capped.
Expiration: 1 Week

Diluent: 30mL of reagent water acidified to a pH <2.0 with 1:1 H_2SO_4. For use in KONE instrument.

3.3 Standards

Hexavalent Chromium Initial Calibration Verification Stock (1000mg/L) – Purchased from Sigma Aldrich.
Expiration: Opened: 1 year or the manufacturer's expiration date, whichever is shorter

Hexavalent Chromium Solution (10mg/L) – Purchased from CPI. Used to prepare calibration standards and matrix spike/ matrix spike duplicates (MS/MSD)
Storage: Opened: 1 year or the manufacturer's expiration date, whichever is shorter

Hexavalent Chromium Calibration Standards

Standard Level	TALS Reagent Name	Parent Standard	Aliquot (mL)	Final Volume (mL)	Final Concentration (mg/L)
1	CR6 CAL 6	10mg/L Cr6 Solution	0.10	100	0.010
2	CR6 CAL 5	10mg/L Cr6 Solution	0.25	100	0.025
3	CR6 CAL 4	10mg/L Cr6 Solution	0.50	100	0.050
4	CR6 CAL 3	10mg/L Cr6 Solution	1.0	100	0.10
5	CR6 CAL 2	10mg/L Cr6 Solution	3.0	100	0.30
6	CR6 CAL 1	10mg/L Cr6 Solution	5.0	100	0.50

Dilute to volume in reagent water. Expiration: 1 month from preparation

Hexavalent Chromium Laboratory Control Sample (LCS) (0.20mg/L) – Dilute 2mL of the 10mg/L Hexavalent Chromium Solution to 100mL with DI water. (Used as CCV and LCS)
Expiration: 1 month from preparation

Hexavalent Chromium ICV Intermediate Standard (10mg/L) – Dilute 1mL of the 1000mg/L CR6 ICV Stock standard to 100 mL with DI water.
Expiration: 1 month from preparation

Hexavalent Chromium Initial Calibration Verification (0.30mg/L) – Dilute 3mL of the 10mg/L CR6 ICV Intermediate standard to 100 mL with DI water.
Expiration: 1 month from preparation

4.0 Sample Preparation

4.1 Aqueous Samples

Aqueous samples are filtered through a 0.45 micron filter prior to analysis. Typically 20 mL of sample are filtered. Add approximately 0.05mL (1 drop) of concentrated H_3PO_4. Adjust the pH of 20mL of sample to pH 1.5–2.5 with 50% H_2SO_4. Use narrow range pH paper during adjustment to verify the proper pH is achieved.

Note: NCMs must be initiated for samples originating in WV that have not been field filtered.

Prepare QC samples in the same manner as field samples as follows:

- Continuing Calibration Verification- prepared as described above
- Continuing Calibration verification Blank – reagent water
- Method Blank – reagent water
- Laboratory Control Sample (LLCS) – prepared as described above.
- Low-Level Laboratory Control Sample (drinking water) – Lowest level standard of the initial calibration
- Matrix Spike/Matrix Spike Duplicate – Add 0.20mL of Hexavalent Chromium Solution (10mg/L) to 10mL of the chosen sample.

5.0 Method-Specific QC Requirements

SM3500-Cr B – Linear Dynamic Range (LDR) study initially. Reporting limit verification per batch. Any sample containing a detection greater than 90% of the determined LDR must be diluted to until the raw result is less than 90% of the determined LDR.

A CCV must be analyzed immediately following the initial calibration (in addition to the ICV). This CCV must recover within 5% of the true value.

An RL check sample must be analyzed at the beginning of each sequence.

6.0 Method-Specific Modifications and Clarifications

6.1 The SM3500-Cr B reference method states to adjust sample pH to 2 +/-0.5 with 0.2N sulfuric acid. The EPA 7196A reference method states to adjust sample pH to 2 +/-0.5 with 10%sulfuric acid. Adjusting the pH with such a weak solution requires adding >5% volume and therefore diluting the sample. As such, the laboratory has chosen to use 50% sulfuric to adjust the sample pH.

6.2 The EPA 7196A reference method states to add the color reagent, then adjust the sample pH to 1.5-2.5. The Konelab instrument automatically adds the color reagent; therefore, the order of these steps is reversed (i.e., the laboratory adjusts the pH then adds the color reagent). Correspondence with EPA indicates this is an acceptable modification to the method.

Attachment 1e
SOP Summary
Ortho-phosphate

1.0 Summary

Orthophosphate reacts with ammonium molybdate and antimony potassium tartrate under acidic conditions to form a complex which, when reduced with ascorbic acid, produces an intense blue color. The color is measured photometrically at 880nm and the absorbance is proportionate to the amount of orthophosphate in the sample.

2.0 Interferences

Samples that are blue in color may interfere. Samples with high concentrations of arsenic may interfere.

3.0 Reagents and Standards

3.1 Purchased Reagents

Antimony Potassium Tartrate [$K(SbO)C_4H_4O_6 \cdot ½\ H_2O$] – reagent grade

Ammonium Molybdate [$(NH_4)_6Mo_7O_{24} \cdot 4H_2O$] – reagent grade. Storage: Isolated from sources of heat and moisture.

Sulfuric Acid (H_2SO_4) – concentrated, A.C.S. grade
Storage: Acid resistant floors and good drainage. Away from sunlight, heat, and water.

Ascorbic Acid – reagent grade
Storage: Isolate from sources of heat and fire.

3.2 Prepared Reagents

Sulfuric acid solution 5N: Slowly add 70mL of concentrated H_2SO_4 to approximately 400mL of reagent water. Cool to room temperature and dilute to 500mL with reagent water.

Antimony Potassium Tartrate Solution – Dissolve 3.0g $K(SbO)C_4H_4O_6 \cdot ½\ H_2O$ in approximately 500mL of reagent water. Dilute to 1000mL with reagent water.
Storage: Store at 4°C in a dark, glass-stoppered bottle.

Ammonium Molybdate Solution – Dissolve 40g $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ in approximately 800mL of reagent water. Dilute to 1L with reagent water.
Storage: Store at 4°C in a plastic bottle.

Color Reagent 2 – Ascorbic Acid Solution (0.1M) – Dissolve 1.76g ascorbic acid in approximately 50mL of reagent water. Dilute to 100mL with reagent water.
Expiration: Prepare fresh daily.

Color Reagent 1 – Add 75mL Ammonium Molybdate Solution to 250mL 5N sulfuric acid. Mix well. Add 25mL Antimony Potassium Tartrate Solution to this solution and mix well.
Expiration: 6 months

Combined Color Reagent – Add 14mL of Color Reagent 1 to 6mL of Color Reagent 2. Mix well.
Expiration: Solution is only good for 4 hours from time of prep.

3.2 Standards

Phosphate Calibration Standard (1000mg/L) – Purchased from NSI Lab Solutions.
Storage: Away from sunlight.
Expiration: Opened: 1 year or the manufacturer's expiration date, whichever is shorter.

Ortho-phosphate Initial Calibration Verification (ICV) Stock (1000mg/L) – Purchased from Inorganic Ventures.
Storage: Away from sunlight.
Expiration: Opened: 1 year or the manufacturer's expiration date, whichever is shorter.

Ortho-phosphate Calibration Standards:

Standard Level	TALS Reagent Name	Parent Standard	Volume of Parent Standard (mL)	Final Volume (mL)	Final Concentration (mg/L)
7	PO4 CAL 1	PO4 100ppm	2	100	2.0
6	PO4 CAL 2	PO4 100ppm	1.6	100	1.6
5	PO4 LCS	PO4 100ppm	1.2	100	1.2
4	PO4 CAL 3	PO4 100ppm	0.8	100	0.80
3	PO4 CAL 4	PO4 100ppm	0.4	100	0.40
2	PO4 CAL 5	PO4 100ppm	0.2	100	0.20
1	PO4 CAL 1 PO4 RL	PO4 100ppm	0.050	100	0.050

Dilute to volume in reagent water.

Ortho-phosphate Laboratory Control Sample (1.2mg/L) – Dilute 1.2mL of 100mg/L Orthophosphate Matrix Spike Solution to a final volume of 100mL with reagent water. (Also used as CCV)
Expiration: 1 month

Ortho-phosphate Initial Calibration Verification (1.0mg/L) – Dilute 1.0mL of the 1000mg/L Ortho-phosphate ICV Stock to a final volume of 1000mL with reagent water.
Expiration: 1 month.

Ortho-phosphate Matrix Spike Solution (100mg/L) – Dilute 10mL of the 1000mg/L Phosphate Calibration Standard to a final volume of 100mL with reagent water.
Expiration: 1 month.

4.0 Sample Preparation

4.1 Aqueous Samples

Aqueous samples are routinely filtered. Filter samples through a 0.45 micron pp filter.

Note: Acidic samples must be neutralized with 1N NaOH prior to analysis.

4.1.1 QC Sample Preparation

-Continuing Calibration Verification – Prepared as described above
-Continuing Calibration Blank – reagent water
-Method Blank – reagent water
-Laboratory Control Sample – Prepared as outlined above
-Low-Level Laboratory Control Sample (Drinking Water only) – Lowest level standard of the initial calibration
-Matrix Spike/Matrix Spike Duplicate – Add 0.10mL of 100mg/L Matrix Spike Solution to 10mL of the chosen sample. The concentration of the MS/MSD must equal the concentration of the LCS.

Prepare all QC in the same manner as samples.

4.2 Soil Samples

Create a DI Leach batch in LIMs.

Weigh approximately 5g of sample into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 100mL of reagent water to each sample container and place in the tumbler.

Rotate for 2 hours +/- 30 minutes.

Remove the containers from the extractor and allow the leachates to settle. Filter the extract using a syringe filter with a 0.45um pore size filter and analyze the extracts as liquid samples.

Add one drop of phenolphthalein indicator solution to approximately 50mL of leachate. If a red color develops add 10N sulfuric acid dropwise until the color dissipates.

Note: Acidic samples must be neutralized with 1N NaOH prior to analysis.

4.2.1 QC Sample Preparation

Method Blank – Weigh approximately 20g of Teflon chips into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g.

Laboratory Control Sample – Weigh approximately 5g of Teflon chips into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 1.0mL of 100mg/L Matrix Spike Solution to the extraction bottle.

Matrix Spike – Weigh an additional 5g aliquot of one of the samples for the MS. Add 1.0mL of 100mg/L Matrix Spike Solution to the extraction bottle. One sample must be chosen from samples 1-10 and one sample from samples 11-20. The concentration of the MS must equal the concentration of the LCS.
Sample Duplicate – If precision is required, weigh one additional 20g aliquot of one of the samples for the SD.

Prepare all QC in the same manner as samples.

5.0 Method-Specific QC Requirements

SM4500-P F requires the MDL study to be analyzed over 3-5 days.

SM4500-P F recommends the matrix spike concentration be rotated.

Attachment 1f
SOP Summary
Sulfate, Total Sulfur, and Heat of Combustion (BTU)

1.0 Summary

Sulfate ion is precipitated in a strongly acidic medium with Barium Chloride. The resulting turbidity is measured photometrically at 405nm and compared with appropriate standard solutions.

Refer to SOP SA-GE-010 for information on the preparation procedures for Total Sulfur and Heat of Combustion (BTU). The attached Work Instruction provides the procedural and calculation information.

2.0 Interferences

Silica at a concentration above 500mg/L in the sample will interfere. Color and turbidity due to the sample matrix can cause positive interferences that must be accounted for by the analysis of sample blanks (i.e. samples analyzed without adding reagents). The absorbance or turbidity of the sample blank is subtracted from the absorbance or turbidity of the treated sample, and the concentration is determined from the corrected response.

3.0 Reagents and Standards

3.1 Purchased Reagents

Barium Chloride ($BaCl_2$) – reagent grade
Storage: Store in a cool, dry, ventilated area. Isolate from heat, moisture, and incompatibles.

Sodium Chloride (NaCl) – reagent grade
Storage: Store in a cool, dry, ventilated area.

Gelatin – (TALS – Gelatin)

Hydrochloric Acid (HCl) – concentrated, A.C.S. grade
Storage: Store in a cool, dry, ventilated area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.

3.2 Prepared Reagents

Precipitating Solution – In a 100mL volumetric flask, dissolve 1.0g $BaCl_2$, 2.0g NaCl, and 0.1g of Gelatin in approximately 30mL reagent water. Stir until completely dissolved. Carefully add 0.5mL concentrated HCl and dilute to volume with reagent water.
Expiration: 3 months

3.3 Purchased Standards

Sulfate Calibration Stock Solution (1000mg/L) – Purchased from Inorganic Ventures.
Expiration: Manufacturer's expiration date.

Sulfate Calibration Standards

Standard Level	TALS Reagent Name	Parent Standard	Volume of Parent Standard (mL)	Final Volume (mL)	Final Concentration (mg/L)
6	SO4 CAL 6	1000mg/L	3.5	100	35
5	SO4 CAL 5	1000mg/L	3.0	100	30
4	SO4 CAL 4	1000mg/L	2.5	100	25
3	SO4 CAL 3	1000mg/L	1.5	100	15
2	SO4 CAL 2	1000mg/L	1.0	100	10
1	SO4 CAL 1	1000mg/L	0.5	100	5

Dilute to volume in reagent water.

Sulfate Laboratory Control Sample (20mg/L) – Dilute 5mL of the 1000mg/L SO4 Cal stock to 250mL final volume.
Expiration: 3 months

Sulfate ICV Stock (1000 mg/L) – Purchased from NSI.
Expiration: Manufacturer's expiration date.

Sulfate Initial Calibration Verification (20mg/L) Add 2.0mL Sulfate Calibration Stock Solution to a 100mL volumetric flask. Dilute to mark with DI water.
Expiration: 3 months

Sulfate Matrix Spike Solution (1000mg/L) – This is the same as the SO4 Calibration Stock Solution
Expiration: Manufacturer's expiration date.

4.0 Sample Preparation

4.1 Aqueous Samples

Aqueous samples are routinely analyzed with no sample preparation.

4.1.1 QC Sample Preparation

Method Blank – reagent water

Laboratory Control Sample – Prepared as outlined above.

Low-Level Laboratory Control Sample (drinking water) – Lowest level standard of the initial calibration

Matrix Spike/Matrix Spike Duplicate – Add 0.2mL of Sulfate Matrix Spike Solution to 10mL of the chosen sample.

Prepare all QC in the same manner as samples

4.2 Soil Samples

Create a DI Leach batch in LIMS.

Weigh approximately 5g of sample into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 100mL of reagent water to each sample container and place in the tumbler.

Rotate for 2 hours +/- 15 minutes.

Remove the containers from the extractor and allow the leachates to settle. Filter the extract using a syringe filter with a 0.450-um pore size filter and analyze the extracts as liquid samples.

4.2.1 QC Sample Preparation
Method Blank – Weigh approximately 5g of Ottawa sand into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g.

Laboratory Control Sample – Weigh approximately 5g of Ottawa sand into a 125mL screw-cap plastic bottle. Record the weight to the nearest 0.1g. Add 2.0mL of Sulfate Cal Stock (1000mg/L) solution and 98mL of DI water.

Matrix Spike/Matrix Spike Duplicate – Weigh two additional 5g aliquots of one of the samples for the MS and MSD. Add 2.0mL of Sulfate Cal Stock (1000mg/L) solution and 98mL of DI water to each bottle.

Prepare all QC in the same manner as samples.

5.0 Method-Specific QC Requirements

A CCV must be analyzed every 3-4 sample analyses (EPA 375.4 Section 6.3.4 and EPA 9038 Section 7.3.4).

6.0 Method-Specific Modifications and Clarifications

6.1 The EPA 375.4 reference method states to measure turbidity every 30 seconds for 1-5 minutes after the addition of barium chloride, with the maximum turbidity reading used for determining the Sulfate concentration. The Konelab instrument performs parallel analyses of each sample - one for performing turbidity measurements and one for sulfate determination. The turbidity measurements are made 200 seconds after the color reagent is added and every 28 seconds after that for 240 seconds. The turbidity absorbances are presented on the raw data to indicate if the sample is settling out but do not affect how the sulfate result is determined. The sulfate determination is made 300 seconds after the color reagent is added. Although the Konelab instrument will allow multiple sulfate readings to be made, the instrument cannot select the result associated with the highest turbidity; rather, it will perform an average of the results obtained. As this instrument configuration cannot be changed to use the sulfate reading taken from the highest turbidity replicate.

6.2 The Sulfate Precipitating Solution is prepared in accordance with the Konelab Application Notes which differs from the information provided in the reference method.

eurofins | Environment Testing TestAmerica

Calculation of Total Sulfur

Method: SW-846 5050 in conjunction with SW-846 9038

Summary of Procedure:

Total sulfur in a sample is determined by oxygen bomb combustion using SOP SA-GE-010: *Bomb Preparation*. The sample is oxidized by electrical ignition in a bomb containing oxygen under pressure. Under these conditions, sulfur is converted to inorganic sulfate and recovered in the DI water bomb washings. Sulfate content is quantitated by using the Konelab (SOP SA-GE-001: *Measurement of Analytes using the Konelab Analyzer)*.

Two fundamental conditions must apply before a sample can be considered to have combusted:

1. Some part of the sample must be heated to its ignition temperature to start the combustion. Then in burning, the sample must liberate sufficient heat to support its own combustion.
2. The combustion must produce enough turbulence within the bomb to bring oxygen into the fuel cup for burning the sample completely.

Calculation:

The calculation of Total Chlorine is performed by the LIMS system.

$$Total\,Sulfur, mg/kg\,dw = \frac{A \times B \times C}{D \times E}$$

Total Sulfur

where

A = mg S/L (mg SO4/L determined by Konelab divided by 3)
B = final volume of bomb washings in liters (0.10L)
C = 1000g/kg conversion factor.
D = sample weight in grams
E = decimal fraction of the percent solids

**NOTE-- Oil matrices will not have a percent solids, therefore the E variable is dropped from the calculation, and the total halogen is reported as mg/kg as is.

Quality Control:

This procedure is a calculation only; therefore, there are no QC items associated. Formal detection limit studies, as described in 40CFR Part 136B and SOP SA-QA-07: *Determination of Detection Limits*, are not required.

Formal demonstrations of capability (DOCs) are described in section 12.2 of SOP SA-GE-010.

eurofins | Environment Testing TestAmerica

Calculation of Heat of Combustion

Method: ASTM D240-87

Summary of Procedure:

The gross heat of combustion in a sample is determined by oxygen bomb combustion using SOP SA-GE-010: *Bomb Preparation*. The sample is oxidized by electrical ignition in a bomb containing oxygen under pressure. Accurate time and temperatures are measured throughout the test period. Under these conditions, sulfur is converted to inorganic sulfate and recovered in the DI water bomb washings. The oxygen bomb washings are titrated for nitric acid formation then analyzed by Konelab (SOP SA-GE-001: *Measurement of Analytes using the Konelab Analyzer)* for sulfate content. Variables from the test period and analytical constants are used to calculate the gross heat of combustion (BTU/lb).

Two fundamental conditions must apply before a sample can be considered to have a heat of combustion:

1. Some part of the sample must be heated to its ignition temperature to start the combustion. Then in burning, the sample must liberate sufficient heat to support its own combustion.
2. The combustion must produce enough turbulence within the bomb to bring oxygen into the fuel cup for burning the sample completely.

Calculation:

A spreadsheet is used to determine the final heat of combustion value.

Energy (Water) Equivalent, W

$$W = \frac{[(H * m) + e1 + e3]}{t}$$

where:

W = energy (water) equivalent of the calorimeter in cal/ °C
H = heat of combustion of standard benzoic acid. (6318 cal/g)
m = weight (mass) of the benzoic acid standard in grams
e1 = correction for heat of formation of nitric acid in cal
e3 = correction for heat of combustion of firing wire in cal

Temperature Rise, t

$$t = tc - ta$$

where:

t = temperature rise in °C
tc = temperature at beginning of period in which the rate of temperature change with time has become constant in °C
ta = temperature at time of firing in °C

Gross Heat of Combustion (BTU/lb), H

$$H = \frac{[(t * W) - e1 - e2 - e3]}{m} * 1.8$$

where:

H =	**gross heat of combustion in BTU/lb**
t =	**temperature rise in °C**
W =	**energy equivalent in cal/ °C**
e1 =	**correction for heat of formation of nitric acid in cal**
e2 =	**correction for heat of formation of sulfuric acid in cal**
e3 =	**correction for heat of combustion of firing wire in cal**
m =	**weight (mass) of sample in grams**
1.8 =	**conversion factor from cal/g to BTU/lb**

Quality Control:

This procedure is a calculation only; therefore, there are no QC items associated. Formal detection limit studies, as described in 40CFR Part 136B and SOP SA-QA-07: *Determination of Detection Limits,* are not required.

Formal demonstrations of capability (DOCs) are described in section 12.2 of SOP SA-GE-010.

The spreadsheet used to determine the heat of combustion result has been verified and protected.

Attachment 2:
Sample Collection, Preservation, and Holding Time Table

Fraction	Matrix	Routine Sample Container	Routine Sample Size	Chemical Preservation	Thermal Preservation	Dechlorination Agent	Holding Time
Ammonia	Water	250mL plastic	40mL	1mL 1:1 H_2SO_4 pH <2	0-6°C[1]	Sodium Thiosulfate	28 Days
Ammonia	Soil	8oz Plastic	20g	None	0-6°C[1]	None	28 Days[2]

Chloride, Total	Water	125mL plastic	1g	None	0-6°C[1]	None	28 Days
Chloride, Total	Soil	8oz Plastic	1g	None	0-6°C[1]	None	28 Days[2]
Ferrous Iron	Water	125mL plastic	10mL	None	0-6°C[1]	None	15 Minutes[3]
Ferric Iron (Calc)	Water	125mL plastic	10mL	None	0-6°C[1]	None	15 Minutes[3]
Hexavalent Chromium	Water	125mL plastic	10mL	None	0-6°C[1]	None	24 Hours[4]

Fraction	Matrix	Routine Sample Container	Minimum Sample Size	Chemical Preservation	Thermal Preservation	Dechlorination Agent	Holding Time
Trivalent Chromium (Calc)	Water	125mL plastic	10mL	None	0-6°C[1]	None	24 Hours
Ortho-Phosphate	Water	125mL plastic	10mL	None	0-6°C[1]	None	48 Hours
Ortho-Phosphate	Soil	8oz Plastic	20g	None	0-6°C[1]	None	48 Hours[2]
Sulfate	Water	125mL plastic	10mL	None	0-6°C[1]	None	28 Days
Sulfate	Soil	8oz Plastic	5g	None	0-6°C[1]	None	28 Days[2]
Sulfur, Total	Water	125mL plastic	1g	None	0-6°C[1]	None	28 Days
Sulfur, Total	Soil	8oz Plastic	1g	None	0-6°C[1]	None	28 Days[2]

[1]Samples must be maintained at 0-6°C, with no frozen samples.
[2] Inclusive of digestion and analysis.
[3] Due to the nature of this analysis, this test is considered a field test. No definitive holding time is specified in the reference methods; however, the Methods Update Rule of 40CFR Part 136 identifies a 15 minute holding time for this method. Although these samples will be outside holding time upon receipt to the laboratory, an effort should be made to analyze as soon as possible after receipt.
[4] Clean Water Act (CWA) sampling requirements state that field filtration must be performed within 15minutes of sampling to prevent interconversion of chromium species. NCMs must be initiated for samples when the COC does not indicate field filtration was performed.

Note: NCMs must be initiated for samples collected in improper containers and containing improper or insufficient preservatives and/or de-chlorination agents.

Attachment 3a: Batch QC Frequency

Fraction	Method	MB Frequency[1]	LCS Frequency[1]	LCSD Frequency[1]	LLCS Frequency[1]	MS Frequency[1]	MSD Frequency[1]	SD Frequency[1]

[1]Batch Definition = Up to 20 field samples prepared and/or analyzed together within 24 hours
[2]If insufficient sample provided for MS/MSD.
[3]For Drinking Water analyses only.

Attachment 3b: QC Summary

QC Item	Frequency	Criteria	Corrective Action
Initial Calibration (ICAL) Multi-point: Minimum 3 standards and 1 blank	Daily	Correlation ≥0.995 And each point on curve must be within +/- 10% of true value	Recalibrate Note: SM3500-Fe B and SM3500-Cr B do not allow quadratic curves
Second Source Initial Calibration Verification (ICV)	Immediately following the initial calibration; at a minimum, quarterly	Within ±10% of the true value	Recalibrate
Continuing Calibration Verification (CCV)	SM3500-Fe B, SM3500-Cr B: Immediately following ICAL Sulfate: At the beginning and end of the analysis, and after every 3-4 samples All Others: At the beginning and end of the analysis, and after every 10 samples	SM3500-Fe B, SM3500-Cr B: Within ±5% of the true value All Others: Within ±10% of the true value	Terminate the analysis, fix the problem and reanalyze the previous samples.
Initial Calibration Blank (ICB)	After ICV	SM3500-Fe B, SM3500-Cr B: <MDL Others: < ½ RL	Terminate the analysis, correct problem and reanalyze the previous 10 samples.
Continuing Calibration Blank (CCB)	After every CCV	SM3500-Fe B, SM3500-Cr B: <MDL	Terminate the analysis, correct problem and reanalyze the previous 10 samples.

QC Item	Frequency	Criteria	Corrective Action
		Others: < ½ RL	
Batch Frequency	<=20 field samples or 24 hours	Not Applicable	Not Applicable
Method Blank (MB)	One per batch	SM3500-Fe B, SM3500-Cr B: <MDL Others: < ½ RL	Evaluate according to SOP SA-QA-017
Laboratory Control Sample (LCS)	One per batch	Within limits listed in the MLG	Evaluate according to SOP SA-QA-017
Laboratory Control Sample Duplicate (LCSD)	One per batch, when insufficient sample provided for MS/MSD/SD	Within limits listed in the MLG	Evaluate according to SOP SA-QA-017
Low-Level Laboratory Control Sample (LLCS)	Drinking Water Only: One per batch	Within limits listed in the MLG	Evaluate according to SOP SA-QA-017
Reporting Limit Verification (RLV)	SM3500-Fe B, SM3500-Cr B: One per batch	Within limits listed in the MLG	Evaluate according to SOP SA-QA-017
Matrix Spike (MS)	Refer to QC Frequency Table	Within limits listed in the MLG	Evaluate according to SOP SA-QA-017
Matrix Spike Duplicate (MSD)	Refer to QC Frequency Table	Within limits listed in the MLG	Evaluate according to SOP SA-QA-017
Sample Duplicate (SD)	Refer to QC Frequency Table	Within limits listed in the MLG	Evaluate according to SOP SA-QA-017
Linear Calibration Range (LCR) (Also called Linear Dynamic Range, LDR)	Upon method/instrument set-up, and when LCR verification fails acceptance criteria.	Within ±10% of the true value	This determines the range at which the instrument is considered linear. The highest concentration of the calibration curve can not exceed the highest concentration of the LCR study.

QC Item	Frequency	Criteria	Corrective Action
Linear Calibration Range Verification (LCRV) (Also called Linear Dynamic Range Verification, LDRV)	Every 6 months	Within ±10% of the initial value	Re-perform the LCR study
Initial Demonstration of Capability (IDOC)	Initially, per analyst, per analyte/method combination	Refer to SOP SA-QA-006	Refer to SOP SA-QA-006 (Unsupervised work cannot begin until successful IDOC is obtained.)
Continuing Demonstration of Capability (CDOC)	Annually, per analyst, per analyte/method combination	Refer to SOP SA-QA-006	Refer to SOP SA-QA-006
Reporting Limit Verification (RLV)	Upon method/instrument set-up, per analyte/method/matrix combination. Then quarterly thereafter for DOD ELAP.	Refer to SOP SA-QA-007	Refer to SOP SA-QA-007
Method Detection Limit Study (MDL)	Upon method/instrument set-up, per analyte/method/matrix combination and annually thereafter EPA 365.1: Upon method/instrument set-up, per analyte/method/matrix combination and every 6 months thereafter	Refer to SOP SA-QA-007	Refer to SOP SA-QA-007

QC Item	Frequency	Criteria	Corrective Action
MDL Verification (MDLV)	Upon method/instrument set-up, per analyte/method/matrix combination. Then quarterly thereafter for methods/analytes on DOD ELAP	Refer to SOP SA-QA-007	Refer to SOP SA-QA-007

Attachment 4: Instrument Maintenance and Troubleshooting

Instrument Labeling

Each instrument must be labeled with its name or ID (e.g., MSA, ICP-D, etc.). Additionally, non-operational instruments must be isolated from service or marked as being out of service. Each piece of equipment has an "Operational / Not Operational" sticker that is used for this purpose.

Maintenance Log

A maintenance log must be established for each piece of equipment used in the laboratory. All maintenance that is performed on the instrument must be recorded in the log including:

- Type of maintenance performed (Note: This includes preventative/routine maintenance; non-routine maintenance; maintenance performed by an external vendor; updates to software versions; etc.)
- Analyst or technician performing the maintenance
- Date the maintenance was performed
- Detailed explanation of the reason for the maintenance
- resolution of the problem and return to control
- All service calls from instrument representatives
- Resolution of the problem (i.e., the Return to Control)

Preventive Maintenance

Refer to the instrument manufacturer's guides for troubleshooting items.

LABORATORY EQUIPMENT PREVENTIVE MAINTENANCE SCHEDULE								
EQUIPMENT ITEM	**Service Interval**							**SERVICE LEVEL**
	D	**W**	**M**	**Q**	**SA**	**A**	**AN**	
Sample Probe	**X**							Clean and inspect daily
Dispenser Rods			**X**					Clean and lube monthly
Fetcher Rods			**X**					Clean and lube monthly
Incubator Rods			**X**					Clean and lube monthly
Water Lines			**X**					Clean with isopropyl alcohol monthly

D = daily; W = Weekly; M = monthly; Q = Quarterly; SA = semi-annually; A = annually; AN = as needed

Contingency Plan

Maintenance contracts are carried for most instrumentation and close contact is maintained with service personnel to ensure optimal instrument functioning. An extensive spare parts inventory is maintained for routine repairs. Since instrumentation is standardized throughout the laboratory network, spare parts and components can be readily exchanged among the network.

In general, the laboratory has at least one backup unit for each critical unit. In the event of instrument failure, portions of the sample load may be diverted to duplicate instrumentation, the analytical technique switched to an alternate approved technique (such as manual colorimetric determination as opposed to automated colorimetric determination), or samples shipped to another properly certified or approved Eurofins Environment Testing location.

Attachment 5: Maximum Contaminant Levels (MCL) Table

Primary Drinking Water Regulations	
Contaminant	**MCL (mg/L)**
Nitrate (as N)	10
Nitrite (as N)	1

Secondary Drinking Water Regulations	
Contaminant	**MCL (mg/L)**
Chloride	250
Sulfate	250

Attachment 6: Glassware Cleaning Procedures

GLASSWARE CLEANING PROCEDURES - GENERAL LAB

MISCELLANEOUS APPARATUS

1. Scrub with hot tap water and Liquinox.
2. Rinse thoroughly with tap water.
3. Rinse at least three times with DI water.
4. Air-dry and store inverted in a cabinet or capped.

NOTE:

1. Do not use soap for cleaning COD digestion tubes.
2. Burets may be cleaned by filling with 10% KOH in methanol, allowing to stand for one hour, then rinsing thoroughly with DI water.
3. Evaporating dishes used for TDS determinations are cleaned by rinsing thoroughly with tap water, soaking for several hours in Nochromix, rinsing thoroughly with tap water, and rinsing three times with DI water. The dishes are then oven-dried.

TKN / TOTAL-P DIGESTION TUBES

1. Scrub with hot tap water and Liquinox.
2. Rinse thoroughly with tap water.
3. Rinse once with Nochromix.
4. Rinse at least three times with DI water.

CYANIDE DISTILLATION APPARATUS

1. Scrub with hot tap water and Liquinox.
2. Rinse thoroughly with tap water.
3. Rinse with 10% nitric acid, being certain to force at least 10mL through each dispersion tube.
4. Rinse thoroughly with DI water.

ODOR-FREE GLASSWARE

1. Scrub with hot tap water and Liquinox.
2. Rinse with acid cleaning solution.
3. Rinse thoroughly with odor-free water.
4. Glassware used in odor testing should be reserved for that purpose only.

FGE003:08.17.18:2

eurofins | Environment Testing TestAmerica

18.0 Revision History

Summary of Changes for Revision 9:
- Removed references to TestAmerica from document.
- Removed references to WV criteria. The laboratory is not certified in WV as of 7/2021.
- Added calibration readback criteria of +/-10% to section 9.2.1.
- Revised blank criteria from <MDL to <1/2RL to be consistent with SM4020. <MDL is the criteria for SM3500 CR –B and Fe-B. Updates to Section 9.2.3 and Attachment 3.
- Updated definition of MDL in section 12.2 to be consistent with SOP SA-QA-007.
- Updated RLV and MDLV requirements.

Summary of Changes for Revision 8:
- Added section 6.2 to reference the Master Equipment Listing Maintained by the QA department.
- Updated section 10.1 that samples for Orthophosphate are filtered prior to analysis.
- Updated section 14.1 that RCRA hazardous and non-hazardous soil samples are disposed via the yardbox for incineration.
- Clarified requirements for Hexavalent Chromium in Attachment 2. Samples must be field filtered within 15minutes of sampling. An NCM must be initiated if no indication on COC of field filtering. WV Audit 2020
- Added pH verification and residual chlorine checks to Attachment 1a for Ammonia.
- Attachment 1c, section 3.3: Updated preparation of Ferrous Iron LCS solution.
- Attachment 1c, section 4.1: Updated sample preparation steps with more details.

Summary of Changes from Previous Revision 7:
- Minor editorial, grammatical, and/or formatting changes made.
- Revised soil sample preparation procedures for chloride. Attachment 1b, Section 4.2
- Revised Company logo and name where applicable

SOLID / RESIDUE DETERMINATIONS

(Methods: Various)

Approvals (Signature/Date):

Kimberly Chamberlain 11/18/2020

1.0 Scope and Application

This SOP contains the procedures for the determination of various residue analytes in water, soil, and waste samples.

The following analytes, matrices, methods, and technologies are included in this SOP:

Analyte	Matrix	Reference Method	Technology
Total Dissolved Solids	Water	EPA 160.1 and SM2540C	Gravimetric
Total Suspended Solids	Water	EPA 160.2 and SM2540D	Gravimetric
Total Solids	Water	EPA 160.3 and SM 2540B	Gravimetric
Volatile Dissolved Solids	Water and Waste (oil)	EPA 160.4 and SM2540E	Gravimetric
Volatile Suspended Solids	Water and Waste (oil)	EPA 160.4 and SM2540E	Gravimetric
Volatile Solids	Water and Waste (oil)	EPA 160.4 and SM2540E	Gravimetric
Fixed Solids	Water and Waste (oil)	EPA 160.4	Gravimetric
Ash Content	Water and Waste (oil)	SM 2540E	Gravimetric
Settleable Solids	Water	EPA 160.5 and SM2540F	Volumetric
Percent Moisture Fixed Solids Total Solids Total Volatile Solids Ash Content	Soil and Waste (oil)	SM2540G	Gravimetric
Percent Moisture Percent Solids (Used for Dry Weight Corrections)	Soil	EPA 3500B EPA 3500C EPA 3550B EPA 3550C	Gravimetric

The reporting limits (RL) and accuracy and precision criteria associated with this procedure are provided in the TALS Method Limit Groups (MLGs).

This SOP was written by and for Eurofins TestAmerica's Savannah laboratory.

2.0 Summary of Method

2.1 Total Solids (TS) – also called Total Residue

A well-mixed sample is transferred to a tared evaporating dish or pre-weighed vessel, and evaporated at 103°C-105°C. The residue that remains after the liquid has been evaporated is the total residue (or total solids) of the sample. The total solids are reported as milligrams of residue per liter of sample (mg/L).

The Total Solids is an approximate measure of the sum of the total suspended solids (TSS) and total dissolved solids (TDS). The total residue may not be equal to the sum of the TSS and TDS since the TDS is determined at 180°C and the total residue is determined at 103°C-105°C.

Note: The procedure used by the laboratory for the determination of percent solids/moisture as it pertains to dry weight determination is performed in a similar manner as the method procedure described above but the method-specified QC steps are not required. Refer to the applicable % Solids/% Moisture Work Instruction (in Attachment 15) for information on this procedure.

2.2 Volatile Solids (VS) and Ash Content/Fixed Solids

After the total solids has been determined, as outlined above, the residue is heated to 550 ± 50°C to determine the volatile solids. The portion of the residue that is lost during the 550°C heating step is defined as the volatile solids.

The residue remaining after heating to 550°C is the ash content or the fixed solids.

2.3 Total Suspended Solids (TSS) – also called Non-filterable Solids/Residue

A well-mixed sample is filtered through a tared glass fiber filter. The residue trapped on the filter pad is dried at 103°C-105°C. The weight of the residue (mg) divided by the volume of the sample filtered (L) is the total suspended solids. The total suspended solids are reported as milligrams of residue per liter of sample (mg/L).

Note: The TSS analysis is also referred to as "non-filterable residue" because the portion of the sample that is trapped on the filter pad is measured.

2.4 Volatile Suspended Solids (VSS)

The volatile suspended solids are determined by placing the filter containing the TSS residue into a muffle furnace at 550 ± 50°C. The portion of the residue that is volatilized at 550°C is the volatile suspended solid.

2.5 Total Dissolved Solids (TDS) – also called Filterable Solids/Residue

A well-mixed sample is filtered through a tared glass fiber filter. The filtrate (the liquid portion passing through the filter) is transferred to a tared evaporating dish or pre-weighed vessel and the liquid is evaporated between 115-125°C. The sample is then transferred to a new oven that is set to 180°C. The residue that remains after the sample has been heated at 180°C is the total dissolved solids portion of the sample. The total dissolved solids are reported as milligrams of residue per liter of sample (mg/L).

Note: The TDS analysis is also referred to as "filterable residue" because the dissolved solids in the portion of the sample that passes through the filter pad is measured.

2.6 Volatile Dissolved Solids (VDS)

The volatile dissolved solids are determined by placing the remaining TDS residue in a muffle furnace at 550°C ± 50°C. The weight that is lost after the sample has been heated at 550°C is the volatile dissolved solids portion of the sample.

Note: VDS determinations (and their associated TDS determination) must be performed using tared evaporating dishes ONLY, as the pre-weighed vessels are not capable of withstanding temperatures of 550 °C ± 50°C and therefore are not approved for VDS methods.

2.7 Settleable Solids – also called Settable Matter

A well-mixed sample is transferred to an Imhoff cone and measured volumetrically.

2.8 This SOP is based on the methods listed in Section 1.

3.0 Definitions

Refer to the Glossary Section of the *Quality Assurance Manual* (QAM) for a complete listing of applicable definitions and acronyms.

4.0 Interferences

4.1 Procedural Interferences

4.1.1 Interferences may be caused by contaminants in solvents, reagents, glassware, and other sample processing apparatus and can make quantification of the target analytes difficult.

4.1.2 All sample collection containers are single-use disposable containers which limits the potential for contamination. All non-disposable labware must be scrupulously cleaned in accordance with the posted Labware Cleaning Instructions to ensure it is free from contaminants and does not contribute artifacts.

4.1.3 High purity reagents and solvents are used to help minimize interference problems.

4.1.4 Instrument and/or method blanks are routinely used to demonstrate all reagents and apparatus are free from interferences under the conditions of the analysis.

4.1.5 Since the basis of the gravimetric procedure is the difference in the weight of the crucible containing the residue and the tare weight of the crucible, care must be taken to ensure that the crucible is not treated in such a manner to add or lose weight. Oils from the hand can be added to the dish by touching the dish with "ungloved" hands.

4.2 Matrix Interferences

4.2.1 For some settleable solids samples a separation of settleable and floating materials will occur. In these instances, the volume attributed to the floating materials is not included in the determination of the final result.

4.2.2 Highly mineralized water containing calcium, magnesium, chloride, or sulfate will require prolonged drying. A crust may form in some samples, trapping water underneath.

4.2.3 An excellent discussion on some of the problems that may be encountered when determining solids is found in Section 2540 of the *Standard Methods for the Examination of Water and Wastewater*, 20th Edition.

5.0 Safety

Employees must abide by the policies and procedures in the Eurofins TestAmerica Environmental Health and Safety Manual (EHSM), the Eurofins TestAmerica Savannah Addendum to the EHSM, and this document.

This procedure may involve hazardous materials, operations, and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user to follow appropriate safety, waste disposal, and health practices under the assumption that all samples and reagents are potentially hazardous.

The analyst must protect himself/herself from exposure to the sample matrix. Many of the samples that are tested may contain hazardous chemical compounds or biological organisms. The analyst must, at a minimum, wear protective clothing (lab coat), eye protection (safety glasses or face shield), disposable nitrile or latex gloves, and closed-toe, nonabsorbent shoes when handling samples.

5.1 Specific Safety Concerns or Requirements

All samples must be treated as if they are hazardous. The analyst must protect himself/herself from exposure to the sample matrix. Many of the samples that are tested for residue/solids may contain hazardous chemical compounds or biological organisms. The analyst must wear protective clothing (lab coat or apron), eye protection (glasses or face shield), and disposable gloves when handling these samples.

The toxicity or carcinogenicity of chemicals used in this method has not been precisely defined. Each chemical should be treated as a potential health hazard, and exposure to these chemicals should be minimized.

The analyst should handle samples that have been dried at or above 180°C with caution. This temperature can cause skin burns and damage to unprotected countertops. Gloves and tongs suitable for handling samples that have been placed in a muffle furnace must be used by the analyst to prevent the severe burns that can occur by contact with samples or containers at or near 550°C. The analyst is cautioned to make sure the surface that sample containers are placed on after removal from the oven or muffle furnace is capable of handling the heat without damage.

5.2 Primary Materials Used

The following is a list of the materials used in this procedure, which have a serious or significant hazard rating, and a summary of the primary hazards listed in their MSDS/SDS.

Note: This list does not include all materials used in the procedure. A complete list of materials used in this procedure can be found in the Reagents and Standards Section and the Equipment and Supplies Section of this SOP

Employees must review the information in the MSDS/SDS for each material before using it for the first time or when there are major changes to the MSDS/SDS. Electronic copies of MSDS/SDS can be found using the "MSDS" link on the Oasis homepage, on the EH&S webpage on Oasis, and through TALS file system shares.

6.0 Equipment and Supplies

6.1 Equipment and Instrumentation

Analytical Balance – Verify in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*

Top-loading Balance – Verify in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*

Portable Conductivity Meter- Verified daily prior to use

Vacuum Pump – with appropriate tubing and water trap

Drying Oven – capable of maintaining a constant temperature of 103-105°C and/or 180°C ± 2°C and/or 115-125 °C.

Muffle Furnace – capable of maintaining a constant temperature of 550 +/- 50°C.

Thermometers – Verify in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*. Note: To ensure full traceability, the thermometer ID and all applicable temperatures (i.e., start, stop, corrected, and uncorrected) must be documented in the Batch Data Types in TALS.

NIST-traceable timer – Verify in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*

6.2 Volumetric Containers and Dispensers

All volumetric labware must be verified in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use).* Refer to Attachment 16 for Labware Cleaning Procedures.

Volumetric Labware	Volume	Type (Quantitative / Qualitative)	Use	Verification Frequency	Laboratory Verification Criteria
Imhoff Cone	1L	QUANTITATIVE	Settable Solids Determination	Initially, prior to use	Accuracy = 2% Precision = 1%
Eppendorf-Style Mechanical Pipettes	Various	QUANTITATIVE	Preparing Dilutions, Standard and Reagent Preparation and Spiking	Initially, prior to first use, then quarterly thereafter (Daily for DOD)	Accuracy = 2% Precision = 1%
Graduated Cylinders (Class A)	Various	QUANTITATIVE	Preparing Dilutions, Standard and Reagent Preparation	None (Class A)	None (Class A)

6.3 Lab Supplies

Filtration Apparatus – consisting of a 47mm filter magnetic funnel and a 1000mL filtrate receiving flask with a sidearm. The filter funnel should extend into the receiving flask to ensure that no filtrate is suctioned into the water trap. (Note: This is especially important if TDS is to be determined on the filtrate.) A rubber or Neoprene stopper is used to attach the filter support to the receiving flask.

Constant weight, binderless glass fiber filter discs; 47-mm. Proweigh Double for TSS / VSS. Part number f93447MM-X (for TSS) and F93447VOL-X (for VSS)

Porcelain evaporating dishes - appropriate volume capacity. The evaporating dishes must be clearly marked so that samples transferred to the dishes can be clearly identified.

Pre-weighed Vessels – can be used in place of porcelain evaporating dishes for TS and TDS analyses only.

Weighing Bracket – for use with pre-weighed vessels, ensures accurate placement of vessel on center of balance platform

Modular Rack – for use transporting pre-weighed vessels to and from the oven

De-ionizing U-electrode and power supply – aids in eliminating static during weigh backs of pre-weighed vessels

Imhoff Cone Holder

Forceps – to handle the filter if TSS is being determined in conjunction with TDS

Aluminum Pans

Desiccator

Spatula or other utensil for transferring sample

Glass Rods

Nochromix – used to clean evaporating dishes and crucibles

Detergent – Liquinox or equivalent, used to wash non-disposable labware

6.4 Sample Collection Containers

All sample collection containers are single-use disposable containers which limits the potential for contamination. The routine samples containers supplied by the laboratory for these tests are listed below:

- 250mL, 500mL, or 1000mL plastic containers (dependent on the test being performed)
- 8oz plastic soil containers – used for SM2540G

All containers must be purchased with Certificate of Analysis attesting to purity. Refer to Attachment 2 for more information on container sizes.

7.0 Reagents and Standards

7.1 Expiration Dates

Expiration dates (time from initial use or receipt to final use) for standard and reagent materials must be set according to the guidance in this SOP. Note: These are maximum expiration dates and are not to be considered an absolute guarantee of standard or reagent quality. Sound judgment must be used when deciding whether to use a standard or reagent. If there is doubt about the quality of a standard or reagent material, a new material must be obtained or the standard or reagent material verified. Data quality must not be compromised to extend a standard's life.

The expiration date of any standard or reagent must not exceed the expiration date of the standard or reagent that was used to prepare it.

7.2 Reagents

Reagents must be prepared and documented in accordance with SOP SA-AN-041: *Reagent and Standard Materials Procedures.*

7.2.1 Laboratory Reagent Water – ASTM Type I

7.2.2 Desiccant – Drierite, blue to light purple color change
Storage: Store in a tightly closed container in a cool, dry location. Store away from incompatible materials.
Expiration: Unopened: Manufacturer's expiration date; Opened: 1year from date opened

7.2.3 Blank Matrix – Ottawa sand or equivalent. Used for the preparation of soil QC samples.
Storage: Room temperature
Expiration: Unopened: Manufacturer's expiration date; Opened: 1year from date opened

7.3 Standards

Standards must be prepared and documented in accordance with SOP SA-AN-041: *Reagent and Standard Materials Procedures.* Certificates of analysis or purity must be received with all purchased standards, and scanned and attached in TALS.

7.3.1 NSI Multi-analyte Solids Standard
Cat#QCI-171

7.3.2 Spectro Pures 1413us/cm for verification of the portable conductivity meter.
Cat#SP0696301A

8.0 Sample Collection, Preservation, Shipment, and Storage

8.1 Aqueous Samples

Aqueous samples are routinely collected in the following containers:
- 250mL, 500mL, or 1000mL plastic containers (dependent on the test being performed)

Samples must be iced at the time of collection and maintained at 0-6°C (less than 6°C but not frozen) until the time of analysis.

Refer to Attachment 2 for additional container and holding time information.

8.2 Soil Samples

Soil samples for SM2540G are routinely collected in 8oz plastic soil containers.

Percent solids samples used for the determination of dry weight are generally subsampled from the Metals or General Department sample portion. If the samples are for volatiles analyses only, then the soil samples are subsampled from the volatiles portion after the Volatiles Department has completed preparation of the sample.

Samples must be iced at the time of collection and maintained at 0-6°C (less than 6°C but not frozen) until the time of analysis.

Refer to Attachment 2 for holding time information.

8.3 Waste (Oil) Samples

Waste (oil) samples for Standard Methods 2540E and 2540G are routinely collected in 4oz amber glass soil containers.

Samples must be iced at the time of collection and maintained at 0-6°C (less than 6°C but not frozen) until the time of analysis.

Refer to Attachment 2 for holding time information.

9.0 Quality Control

SOP SA-QA-017: *Evaluation of Batch QC Data* and the SOP Summary in Attachment 3 provide requirements for evaluating QC data.

9.1 Batch QC

An analytical batch consists of up to 20 environment samples and the associated quality control (QC) items.

The default QC items performed for each analytical batch for this procedure are: a method blank and two separate sample duplicates; i.e., a minimum of 1 sample duplicate per 10 samples, equivalent to a 10 % frequency. The following methods also incorporate a laboratory control sample (LCS): EPA 160.1 and SM2540C, EPA 160.2 and SM2540D, and EPA 160.3 and SM2540B.

If there is insufficient sample to perform the sample duplicates, an NCM must be initiated. Note: Do not use field QC samples such as the equipment blank or field blank to perform the sample duplicates.

Batch QC must meet the criteria given in Attachment 3 of this SOP.

9.2 Method-Specific QC

For the VSS procedure, each lot of fiber filters must be tested prior to use to verify the suitability of the filter. This verification is performed by the vendor and a certificate is available from the vendor website.

9.3 Constant Weight Determination Procedures

For all residue determinations except percent solids/moisture, the constant weight must be achieved. If a constant weight cannot be achieved, the sample must undergo additional drying and weighing cycles until the constant weight criteria are achieved. An NCM must be initiated if constant weight is not achieved after three weighing.

Refer to Attachment 14 for these procedures and criteria.

9.4 Corrective Action for Out-of-Control Data

When the quality control parameters do not meet the criteria set forth in this SOP, corrective action must be taken in accordance with SOP SA-QA-005: *Preventive and Corrective Action Procedures* and the QC Summary Table in Attachment 3.

SOP SA-QA-005 provides contingencies for out-of-control data and gives guidance for exceptionally permitting departures from approved policies and procedures.

Nonconformance Memos must be initiated to document all instances where QC criteria are not met and all departures from approved policies and procedures.

10.0 Procedure

10.1 Field Sample Preparation

See Attachments 5 – 15 for details on field sample preparation.

10.2 QC Sample Preparation

See Attachments 5 – 15 for details on QC sample preparation.

10.3 Analysis

See Attachments 5 – 15 for details on sample analysis.

11.0 Calculations / Data Reduction

11.1 Data Reduction

Data must be evaluated in accordance with SOP SA-QA-002: *Data Generation and Review.*

11.1.1 These tests are empirical tests; therefore, there are no data reduction steps specific to these procedures.

11.1.2 Historical Data

Many of the laboratory's clients submit samples for repeat monitoring purposes. Prior to analysis, verify TALS Worksheet Notes and/or use the Historical Data Tracker feature to determine if historical data is available for review.

11.1.3 Chemical Relationships

When available, the following chemical relationships must be evaluated for each sample. If these relationships are not met the Department Manager must be contacted immediately.

- Total Solids (TS) ≥ TDS or TSS
- TDS ≥ individual anions

11.2 Calculations

11.2.1 The calculations associated with batch QC determinations are given in SOP SA-QA-017. Applicable calculations include accuracy (% recovery) and precision (%RPD).

11.2.2 The calculations associated with each analyte/method are contained in Attachments 5 through 15.

12.0 Method Performance

12.1 Reporting Limit Verification (RLV)

At a minimum, RLVs must be performed initially upon method set-up in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits*. The reporting limit is based on the lowest discernable value achievable by the labware used in this procedure.

For analytes and methods certified by DOD ELAP, RLVs must also be performed quarterly thereafter. For all other analytes and methods, RLVs must also be performed annually thereafter. Exceptions may be made for project-specific non-routine analytes.

12.2 Method Detection Limit Study (MDL)

Method detection limits as generated in accordance with 40CFR Part 136 Appendix B are not applicable to this procedure. The reporting limit is based on the lowest discernable value achievable by the labware used in this procedure.

12.3 Method Detection Limit Verification (MDLV)

MDL verifications as outlined in SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits* are not applicable to this procedure. The reporting limit is based on the lowest discernable value achievable by the labware used in this procedure.

12.4 QC Limit Generation, Control Charting, and Trend Analysis

The control limits for the batch QC items (i.e., LCS/LCSD and SD) for this procedure are not specified by the reference methods; therefore, the laboratory defaults to in-house and/or laboratory-derived limits for the evaluation of batch QC items.

Although the laboratory must default to the method-defined QC limits, control charting is a useful tool and is performed to assess analyte recoveries over time to evaluate trends. Control charting must be performed periodically (at a minimum annually) in accordance with SOP SA-QA-017: *Evaluation of Batch QC Data*.

12.5 Demonstrations of Capability

Initial and continuing demonstration of capability must be performed in accordance with SOP SA-QA-006*: Training Procedures.*

Prior to performing this procedure unsupervised, each new analyst who performs this analysis must demonstrate proficiency per method by successful completion of an initial demonstration of capability.

The IDOC is performed by the analysis of 4 consecutive LCSs that meet the method criteria for accuracy and precision, or, when LCS are not available, by the analysis of client samples with statistically indistinguishable results when compared to another certified analyst. The IDOC must be documented and routed to the QA Department for filing.

Annual continuing demonstrations of capability (CDOCs) are also required per analyst per method/analyte combination. The CDOC requirement may be met by via the consecutive analysis of four LCS (where available) all in the same batch, by the analysis of four LCS analyzed in four consecutive batches (in different batches on different days), acceptable results on a PT study or by the analysis of client samples with statistically indistinguishable results when compared to another certified analyst. The CDOC must be documented and routed to the QA Department for filing.

12.6 Training Requirements

All training must be performed and documented in accordance with SOP SA-QA-006: *Training Procedures*.

Note: The SOPs listed in the Reference/Cross-Reference Section are applicable to this procedure. All employees performing this procedure must also be trained on these SOPs, and/or have a general understanding of these procedures, as applicable.

13.0 Pollution Control

It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (e.g., examining recycling options, ordering chemicals based on quantity needed, preparing reagents based on anticipated usage and reagent stability, etc.). Employees must abide by the policies in Section 13 of the Environmental Health and Safety Manual and the Savannah Addendum to the EHSM.

This procedure has been evaluated for opportunities to minimize the waste generated. Where reasonably feasible, pollution control procedures have been incorporated.

14.0 Waste Management

Waste management practices must be conducted consistent with all applicable federal, state, and local rules and regulations. All waste (i.e., excess reagents, samples, and method process wastes) must be disposed of in accordance with Section 9 of the Eurofins TestAmerica Savannah Addendum to the EHSM. Waste description rules and land disposal restrictions must be followed.

14.1 Waste Streams Produced by the Method

The following waste streams are produced when this method is carried out:

- Non-hazardous acidic and alkaline wastewater and samples – Neutralize before disposal into drain/sewer system
- Excess aqueous samples – Dispose according to characterization on the sample disposal sheets. Neutralize non-hazardous samples before disposal into drain/sewer. Transfer hazardous samples (identified on disposal sheets) to the waste department for disposal.
- Acidic rinsings – Neutralize before disposal into drain/sewer system
- Excess soil and solid samples – Dispose according to characterization on sample disposal sheets. Transfer non-hazardous and RCRA hazardous samples to waste department for disposal via yard box. This yard box is incinerated by the waste disposal company. Transfer samples classified as PCB Hazardous or Foreign Soils to the waste department for disposal via drumming.

16.0 Method Modifications and Clarifications

16.1 Clarification: EPA 160.5 and SM2540F do not specify batch QC requirements. To comply with NELAC and/or state-specific batch QC requirements, the laboratory performs a method blank and a sample duplicate with each batch.

16.2 Clarification: SM2450F gives volumetric and gravimetric procedures for the determination of settleable matter. The laboratory only performs the volumetric procedure.

16.3 Clarification: The gravimetric analytical methods call for drying samples for a minimum of 1 hour. The laboratory's standard procedure is to dry samples for a minimum of 4 hours. The filters are placed back in the oven for an additional hour or overnight to evaluate if a constant weight has been achieved.

16.4 Modification: Although samples comprised of a waste matrix are not addressed in the Standards Methods reference methods, the laboratory has adapted these methods to accommodate waste samples.

16.5 Clarification: With the exception of the Settleable Matter, the EPA reference methods do not specify holding times for these analyses; rather, these reference methods state to perform the test "as soon as possible". The Standard Methods reference methods state to perform the test "as soon as possible" preferably within 24 hours, but no longer than 7 days. As such, the laboratory has adopted a 7-day holding time for all these analyses.

16.6 Modification: The laboratory's procedures for Percent Solids/Percent Moisture used to determine dry weight correction are taken from EPA 3500B, EPA 3500C, EPA 3550B, and EPA 3550C. These procedures are performed in a similar manner as the EPA 160.3 and SM2540B and SM2540G method procedures; however, those method-specified QC steps are not required.

16.7 Modification: Although the associated reference methods (SM2540C, SM2540B, EPA 160.1, and EPA 160.3) do not cite an alternative to the use of porcelain evaporating dishes, new pre-weighed vessels (e.g., StableWeigh) have since been developed and may be used in place of porcelain evaporating dishes for TDS and TS analyses only.

17.0 Attachments

Sample Preparation and Analysis Summary

Total Solids (TS) – also called Total Residue
A well-mixed sample is transferred to a tared evaporating dish or pre-weighed vessel, and evaporated at 103°C-105°C. The residue that remains after the liquid has been evaporated is the total residue (or total solids) of the sample. The total solids are reported as milligrams of residue per liter of sample (mg/L).

The Total Solids is an approximate measure of the sum of the total suspended solids (TSS) and total dissolved solids (TDS). The total residue may not be equal to the sum of the TSS and TDS since the TDS is determined at 180°C and the total residue is determined at 103°C-105°C.

Note: The procedure used by the laboratory for the determination of percent solids/moisture as it pertains to dry weight determination is performed in a similar manner as the method procedure described above but the method-specified QC steps are not required.

Volatile Solids (VS) and Ash Content/Fixed Solids
After the total solids has been determined, as outlined above, the residue is heated to 550 ± 50°C to determine the volatile solids. The portion of the residue that is lost during the 550°C heating step is defined as the volatile solids.

The residue remaining after heating to 550°C is the ash content or the fixed solids.

Total Suspended Solids (TSS) – also called Non-filterable Solids/Residue
A well-mixed sample is filtered through a tared glass fiber filter. The residue trapped on the filter pad is dried at 103°C-105°C. The weight of the residue (mg) divided by the volume of the sample filtered (L) is the total suspended solids. The total suspended solids are reported as milligrams of residue per liter of sample (mg/L).

Note: The TSS analysis is also referred to as "non-filterable residue" because the portion of the sample that is trapped on the filter pad is measured.

Volatile Suspended Solids (VSS)
The volatile suspended solids are determined by placing the filter containing the TSS residue into a muffle furnace at 550 ± 50°C. The portion of the residue that is volatilized at 550°C is the volatile suspended solid.

Total Dissolved Solids (TDS) – also called Filterable Solids/Residue
A well-mixed sample is filtered through a tared glass fiber filter. The filtrate (the liquid portion passing through the filter) is transferred to a tared evaporating dish or pre-weighed vessel and the liquid is evaporated at 115-125°C. The samples are then moved to an oven that is heated to 180°C± 2°C. The residue that remains after the sample has been heated at 180°C is the total dissolved solids portion of the sample. The total dissolved solids are reported as milligrams of residue per liter of sample (mg/L).

Note: The TDS analysis is also referred to as "filterable residue" because the dissolved solids in the portion of the sample that passes through the filter pad is measured.

Volatile Dissolved Solids (VDS)
The volatile dissolved solids are determined by placing the remaining TDS residue in a muffle furnace at 550°C ± 50°C. The weight that is lost after the sample has been heated at 550°C is the volatile dissolved solids portion of the sample.

Note: VDS determinations (and their associated TDS determination) must be performed using tared evaporating dishes ONLY as the pre-weighed vessels are not capable of withstanding temperatures of 550 °C ± 50°C therefore are not approved for VDS methods.

Settleable Solids – also called Settable Matter
A well-mixed sample is transferred to an Imhoff cone and measured volumetrically.

Attachment 4:
Preventative Maintenance and Troubleshooting

Instrument Labeling

Each instrument must be labeled with its name or ID (e.g., MSA, ICP-D, etc.). Additionally, non-operational instruments must be isolated from service or marked as being out of service. Each piece of equipment has an "Operational / Not Operational" sticker that is used for this purpose.

Maintenance Log

A maintenance log must be established for each piece of equipment used in the laboratory. All maintenance that is performed on the instrument must be recorded in the log including:

- Type of maintenance performed (Note: This includes preventative/routine maintenance; non-routine maintenance; maintenance performed by an external vendor; updates to software versions; etc.)
- Analyst or technician performing the maintenance
- Date the maintenance was performed
- Detailed explanation of the reason for the maintenance
- resolution of the problem and return to control
- All service calls from instrument representatives
- Resolution of the problem (i.e., the Return to Control)

Desiccator Checks, Maintenance, and Use

The following checks must be performed daily:

- Desiccant is active.
- Hygrometer is in the low humidity zone.
- Door is making an air-tight seal.

The desiccator door must remain closed and seated whenever possible. When the desiccant turns from blue to light purple, discard desiccant and refill pan with fresh desiccant. The desiccant must be disposed in accordance with the Waste Disposal Section of the Eurofins TestAmerica Savannah Addendum to the Environmental Health and Safety Manual.

Attachment 5:

Total Solids (TS) Procedures
EPA 160.3 and SM2540B

Preparation of the Evaporating Dishes

If needed, thoroughly clean the 100mL porcelain evaporating dishes that will be required for the determination of VS (volatile solids). It may be necessary to place Nochromix in the dish for a short time to remove dissolved solids from a previous analysis.

Rinse the evaporating dishes thoroughly with reagent water and allow them to dry. The evaporating dishes should be placed in the oven at 180°C to facilitate the drying.

After the evaporating dish has remained in the oven at 180°C for a minimum of two hours, remove the dishes from the oven and place in the desiccator. Do not close the door of the desiccator completely until the dishes have cooled. After the dishes have cooled, close the door of the desiccator. The evaporating dishes may be stored in the desiccator until ready for use.

Note: If the evaporating dishes are placed into the desiccator while hot and the door is sealed, a vacuum may form as the dishes cool. If this occurs, the door of the desiccator may be difficult to open.

Note: No preparation is required if utilizing the 200mL pre-weighed vessels in place of the porcelain evaporating dishes. These may be used if only TS is determined.

Determination of Total Solids

Verify that the analytical balance is working within the proper parameters in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*.

Remove the evaporating dish from the desiccator and weigh it on the analytical balance. Record the evaporating dish ID and the weight of the dish to the nearest 0.0001g in the TALS AD batch.

Note: Remember never to touch dishes with bare hands as this can cause oils to deposit and affect the weight of the dish.

Note: If utilizing pre-weighed vessels in place of porcelain evaporating dishes, no initial weight is required. Record the vessel ID and vessel weight found stamped on each individual vessel in the TALS AD batch. Transport vessels to and from the oven using a modular rack.

Mix the sample well before pouring sample into a Class A graduated cylinder. Record the volume of sample in the TALS AD batch.

Note: The sample aliquot to be used in the determination of total residue may be estimated from the specific conductance. If the conductance is greater than 200umho/cm refer to the chart in Attachment 9 for appropriate sample volume. If the conductance is

less than 200umho/cm, use 200mL of sample. If the concentration of the suspended particulates of the sample is significant, a smaller aliquot should be used.

Carefully add the sample to the tared evaporating dish (up to 100mL) or a pre-weighed vessel (up to 200mL). A few milliliters of reagent water must be used to help transfer any particulates adhering to the side of the graduated cylinder to the sample container. Place the sample container into the drying oven maintained at 103°C-105°C to evaporate the liquid portion of the sample. This will generally require overnight in the oven.

After the liquid has evaporated, remove the sample containers from the oven, allow them to cool slightly, and place them in the desiccator. Remember not to place the sample containers on a surface that can cause dirt or other foreign objects to adhere to them. After the containers are cool, place them in the desiccator.

Allow the sample containers to remain in the desiccator until completely cool. Remove from the desiccator and weigh to constant weight using the procedure outlined in Attachment 14.

The Total Solids is calculated using the following equation:

$$TS, mg/L = \frac{(A - B)}{V} \otimes 1000 mg/g$$

Where:
A = weight of sample residue and evaporating dish (g)
B = weight of evaporating dish (g)
V = volume of sample used to determine the TS (L)

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank, one laboratory control sample, and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 100mL or 200mL of reagent water to serve as the blank matrix.

For the laboratory control sample, follow the procedures outlined above and use 50mL of the Multi-analyte solids standard.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 6:

Volatile Solids (VS), Ash Content, and Fixed Solids Procedures EPA 160.4 and SM2540E

Preparation of the Evaporating Dishes for Volatile Solids

Thoroughly clean the 100mL porcelain evaporating dishes that will be required for the determination of VS, Ash Content or Fixed Solids. It may be necessary to place Nochromix in the dish for a short time to remove dissolved solids from a previous analysis.

Rinse the evaporating dishes thoroughly with reagent water and allow them to dry. The evaporating dishes should be placed in the oven at 180°C to facilitate the drying.

After the evaporating dish has remained in the oven at 180°C for a minimum of two hours, remove the dishes from the oven and place them into the muffle furnace. Turn on the muffle furnace, and elevate the temperature 100°C per hour until it reaches 550°C ± 50°C. After one hour at 550°C, remove the dishes from the muffle furnace, allow them to cool for a few minutes, and place them in the desiccator. Do not close the door of the desiccator completely until the dishes have cooled. After the dishes have cooled, close the door of the desiccator. The evaporating dishes may be stored in the desiccator until ready for use.

Note: If the evaporating dishes are placed into the desiccator while hot and the door is sealed, a vacuum may form as the dishes cool. If this occurs, the door of the desiccator may be difficult to open.

Determination of Volatile Solids, Ash Content, and Fixed Solids

Once the Total Solids has been determined per Attachment 5, place the evaporating dish containing the sample residue into the muffle furnace. Turn on the muffle furnace, and elevate the temperature 100°C per hour until it reaches 550°C ± 50°C.

After one hour at 550°C, remove the evaporation dishes from the muffle furnace, allow them to cool for a few minutes, and place them in the desiccator. Remember not to place the evaporating dishes on a surface that can cause dirt, or other foreign objects, to adhere to the dishes or on a surface that will melt when hot dishes are placed on it.

Allow the evaporating dishes to remain in the desiccator until completely cool.

Note: Remember never to touch dishes with bare hands as this can cause oils to deposit and affect the weight of the dish.

Verify that the analytical balance is working within the proper parameters in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*.

Weigh the dishes to constant weight using the procedure outlined in Attachment 14. Record the weight of the dish in the TALs worksheet and calculate the residue to the nearest 0.0001g.

The Volatile Solids is calculated:

$$VS,mg/L = \frac{(R_{105} - R_{550})}{V} \otimes 1000mg/g$$

Where:
V = volume of sample analyzed
R_{550} = (weight of residue and dish at 550°C)g - (weight of dish)g
R_{105} = (weight of residue and dish at 105°C)g - (weight of dish)g

The Fixed Solids is calculated:

$$mg_fixed_solids/L = \frac{(R_{550})}{V} \otimes 1000mg/g$$

Where:
V = volume of sample analyzed
R_{550} = (weight of residue and dish at 550°C)g - (weight of dish)g

The Ash Content is calculated:

$$Ash_Content\% = \frac{R_{550}}{R_{105}} \otimes 100$$

Where:
R_{550} = (weight of residue and dish at 550°C)g - (weight of dish)g
R_{105} = (weight of residue and dish at 105°C)g - (weight of dish)g

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 100mL for porcelain dishes or 200mL for pre-weighed vessels of reagent water to serve as the blank matrix.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 7:

Total Suspended Solids (TSS) Procedures
EPA 160.2 and SM2540D

Preparation of the Filters

Filters are purchased from an approved vendor and are pre-prepared according to method requirements. According to SM 2540 D, 47mm binderless glass fiber filters are washed 3 times in deionized water, dried at 103 - 105°C, and weighed to 0.1mg. The drying and weighing steps are then repeated to guarantee constant weight.

Determination of Total Suspended Solids

Calibrate and verify that the analytical balance is working within the proper parameters in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*.

The filters purchased as pre-weighed contain a number aluminum pan and filter tare weight. The barcode is scanned into the analytical batch to record the ID and filter tare weight.

Assemble the filtration apparatus consisting of a 47mm filter magnetic funnel and a 1000mL filtrate receiving flask with a sidearm. The filter funnel should extend into the receiving flask to ensure that no filtrate is suctioned into the water trap. (This is especially important if TDS is to be determined on the filtrate.) A rubber or Neoprene stopper is used to attach the filter support to the receiving flask.

Using forceps, transfer a filter from the numbered aluminum pan to the filter support with the rough side up. Clamp the filter into place and add a small aliquot (~5mL) of reagent water to the filtering apparatus to seat the filter.

Mix the sample well. Transfer an all or an aliquot of the well-mixed sample to a class A graduated cylinder. Record the sample identification, pan number, and volume of sample in the TALS AD batch.

Note: Use a sample size of 1mL to 1L that will produce a residue within the range of 2.5mg to 200mg, with a target residue of 100mg. 1L should be used for samples without historical data and samples that do not appear to contain suspended residue. Smaller aliquots can be used for samples suspected to contain significant suspended residue.

- If greater than 200mg of residue is obtained, the test must be re-performed using a smaller aliquot of sample. If the test cannot be re-performed using a smaller aliquot, then an NCM must be initiated to denote this situation.
- If less than 1L is used, and less than 2.5mg of residue is obtained, the test must be re-performed using a larger volume of sample (up to 1L). If the test cannot be re-performed using a larger volume, initiate an NCM to denote this situation.

Note: Wide bore pipettes can also be used to transfer the aliquot from the sample container to the filtration device. Narrow bore pipettes must not be used.

Turn on the pump and carefully pour the entire sample aliquot into the filter funnel. Use a small aliquot of reagent water to rinse the entire sample out of the graduated cylinder and onto the filter. Use three 10mL portions of reagent water to rinse down the sides of the filter funnel to transfer all of the particulates on to the filter.

Allow the pump to remain on for about a minute after all of the particulates have been transferred to the filter to remove the water trapped on the filter.

Turn off the pump and release the vacuum. Carefully remove the filter disc from the filter support with the forceps and place the filter in the aluminum pan. The filter should be placed on the edge of the aluminum pan so that the filter has minimum contact with the pan.
Dry the filter at 103°C-105°C for at least one hour, preferably overnight. Record the temperature of the oven corrected and uncorrected, oven ID, thermometer ID and the time that the samples are placed into the oven in the TALS AD batch.

Remove the filters and pans from the oven and place them into the desiccator. Record the oven temperature uncorrected and corrected, and time removed from the oven in the TALS batch.

Place an aluminum pan onto the analytical balance and tare. Using forceps, transfer the filter to the tared aluminum pan. Record the filter weight into the analytical batch and calculate the residue. Weigh the filter to constant weight using the procedure outlined in Attachment 14.

The Total Suspended Solids is calculated using the following equation:

$$TSS, mg/L = \frac{(A - B)}{V} \otimes 1000 mg/g$$

Where:
A = weight of pan, sample residue, and filter (g)
B = weight of pan and filter (g)
V = volume of sample used to determine the TSS (L)

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank, one laboratory control sample, and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 1L of reagent water to serve as the blank matrix.

For the laboratory control sample, follow the procedures outlined above and use 50mL of the TSS Check Standard.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 8:

Volatile Suspended Solids (VSS) Procedures
EPA 160.4 and SM2540E

Preparation of the Filters

Filters are purchased from an approved vendor and are pre-prepared according to method requirements. According to SM 2540 D, 47mm binderless glass fiber filters are washed 3 times in deionized water, dried at 550°C, and weighed to 0.1mg. The drying and weighing steps are then repeated to guarantee constant weight.

Note that these filters will be used to determine the Total Suspended Solids and the Volatile Suspended Solids.

Determination of Volatile Suspended Solids

Volatile suspended solids are the difference in the residue at 105°C (TSS) and the residue that remains after the sample is volatilized at 550°C. The associated TSS method blank must be taken through the ignition procedure described in this section. If the sample was analyzed in duplicate for TSS, both replicates must be taken though the ignition procedure.

After the TSS has been determined, carefully transfer the numbered aluminum pan, filter, and residue into the muffle furnace. If there is quite a bit of organic material in the TSS residue, potentially harmful gases may evolve as the sample ignites. The muffle furnace should be maintained under a hood or in a well ventilated area.

Note: Long handled tongs and proper gloves must be used when working with the muffle furnace.

Turn on the muffle furnace, and elevate the temperature 100°C per hour until it reaches 550°C ± 50°C. Allow the sample to remain in the muffle furnace for at least one hour at 550 ± 50°C. Record the time, temperature that is uncorrected and corrected, and oven ID and thermometer ID the TALs batch once the oven has reached 550 ± 50°C.

After one hour, remove the pans and filters from the furnace and place them on a non-reactive surface to cool slightly. Record the time, temperature that is uncorrected and corrected in the TALs analytical batch. Transfer the pans and filters to the desiccator and allow them to cool to ambient temperature.

Note: Be careful when placing the pans on any surface when they are taken out of the muffle furnace. Even though the heat will quickly dissipate, the pans/filters will be very hot and should not be placed on a surface that will melt or ignite.

Place an aluminum pan on the analytical balance and tare. Transfer the filter containing the residue into the tared aluminum pan. Weigh the filter to constant weight using the procedure outlined in Attachment 14.

Note: Caution must be taken when handling a filter that contains residue. The analyst must be careful not to lose any of the residue. If an obvious loss occurs, contact the department manager and repeat the analysis.

The Volatile Suspended Solids is calculated as follows:

$$VSS(mg/L) = = \frac{(R_{105} - R_{550})}{V} \otimes 1000mg/g$$

Where:
R_{105} = residue at 105°C (g)
R_{550} = residue at 550°C (g)

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 1000mL of reagent water to serve as the blank matrix.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 9:

Total Dissolved Solids (TDS) Procedures
EPA 160.1 and SM2540C

Preparation of the Evaporating Dishes – Used for VDS procedure

Prepare the 100mL porcelain evaporating dishes that will be required for the determination of VDS (Volatile Dissolved Soils) if needed. It may be necessary to place Nochromix in the dish for a short time to remove dissolved solids from a previous analysis.

Rinse the evaporating dishes thoroughly with reagent water and allow them to dry. The evaporating dishes should be placed in the oven at 180°C to facilitate the drying.

After the evaporating dish has remained in the oven at 180°C for a minimum of two hours, remove the dishes from the oven and place in the desiccator. Do not close the door of the desiccator completely until the dishes have cooled. After the dishes have cooled, close the door of the desiccator. The evaporating dishes may be stored in the desiccator until ready for use.

Note: If the evaporating dishes are placed into the desiccator while hot and the door is sealed, a vacuum may form as the dishes cool. If this occurs, the door of the desiccator may be difficult to open.

Note: VDS determinations (and their associated TDS determination) must be performed using tared evaporating dishes ONLY, as the pre-weighed vessels are not capable of withstanding temperatures of 550 °C ± 50°C and therefore are not approved for VDS methods.

Determination of Total Dissolved Solids

Calibrate and verify that the analytical balance is working within the proper parameters in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*.

Note: If TSS is to be determined along with the TDS, the filter used in the filtration step should be prepared in accordance with Attachment 7.

If determining VSS, measure the weight of the pre-labeled, pre-cleaned porcelain dishes to the nearest 0.1mg on an analytical balance and record as the tare weight in the analytical batch.

Note: If utilizing pre-weighed vessels in place of porcelain evaporating dishes, for TDS, no initial weight is required. Record the vessel ID and vessel weight found stamped on each individual vessel in the TALS AD batch. Transport vessels to and from the oven using a modular rack.

A sample's conductivity can be used as a screening test for TDS. Measure the conductivity of the unfiltered samples. If the specific conductance of the sample is less than 200umho/cm, filter 200mL of the sample. The maximum capacity of the preweighed vessels is 200mL. If the specific conductance is greater than 200umho/cm, filter and

analyze an aliquot of sample as outlined in the table below. Record the specific conductivity in the TALS AD batch.

Conductivity (umho/cm)	Sample Volume (mL)
0-200	200
201-2000	50
2001-4000	25
4001-6000	10
>6000	5
>10,000	1

Note: The volume used for analysis must produce a TDS residue between 2.5mg and 200mg.

If greater than 200mg residue is obtained, the sample must be re-analyzed utilizing a larger dilution (i.e., a smaller sample volume).

If less than 2.5mg of residue was determined utilizing a reduced volume of sample (less than 200mL), repeat the test using a volume of sample up to 200mL. If a minimum of 2.5mg of residue is not achieved utilizing 200mL of sample document with an NCM.

Procedure:

Assemble the filtration apparatus.
Place a filter pad in the filter support with the rough side up. If determining TSS on the same sample, transfer a tared filter from the numbered aluminum pan to the filter support with the rough side up. Clamp the filter into place and add a small aliquot (~5mL) of reagent water to the filtering apparatus to seat the filter.

Mix the sample well before taking an aliquot for analysis. Transfer the aliquot, determined by specific conductance above, of the well mixed sample to a graduated cylinder. Do not use a narrow bore pipette to measure the aliquot if TSS is also being determined because a pipette may strain some of the particulates out of the sample aliquot. Record the sample identification, dish number, and volume of sample in the TALS AD batch.

Note: The volume needed for the TSS and the volume of sample needed for the TDS may be different. A sample with a low conductivity but containing a high concentration of suspended solids may require several filters to obtain the needed volume of sample for TDS. In this case, the TSS and TDS should not be analyzed from the same sample aliquot. The sample aliquot must be selected to give a TDS residue of less than or equal to 200mg.

Remove the evaporating dish from the desiccator and weigh it on the analytical balance. Record the evaporating dish ID and the weight of the dish to the nearest 0.0001g in the TALS AD batch.

Note: If utilizing pre-weighed vessels in place of porcelain dishes, no initial weight is required. Record the vessel ID and vessel weight found stamped on each individual vessel in the TALS AD batch. Transport vessels to and from the oven using a modular rack.

Turn on the pump and carefully pour the entire sample aliquot into the filter funnel. Use a small aliquot of reagent water to rinse the entire sample out of the graduated cylinder and on to the filter. Use another small portion of reagent water to rinse down the sides of the filter funnel to transfer all of the particulates onto the filter.

Allow the pump to remain on for a few moments after all of the particulates have been transferred to the filter to remove the water trapped on the filter.

Turn off the pump and release the vacuum. If TSS is being determined concurrently, carefully remove the filter disc from the filter support with the forceps and place the filter in an aluminum pan. Transfer the filtrate from the receiving flask to a properly labeled container.

Note: The entire filtrate must be used for the determination of TDS; that is, the sample filtrate and the reagent water used to rinse the graduated cylinder and the receiving flask are included in the aliquot for TDS. Since the reagent water contains very low concentrations of dissolved solids, the addition of small quantities of reagent water will have no net effect on the concentration of TDS in the sample.

Carefully add the filtered sample to the appropriate tared evaporating dish or pre-weighed vessel and place it in the drying oven maintained at 115°C to 125°C to evaporate the liquid portion of the sample. This will generally require overnight in the oven. Record the time, the temperature that is uncorrected and corrected, thermometer ID and the oven ID in the TALs batch.

After the sample has evaporated, transfer the sample to an oven than has been heated to 180°C ± 2°C and heat for a minimum of 2 hours. Record the time, the temperature that is uncorrected and corrected, thermometer ID and the oven ID in the TALs batch.

Remove the sample containers from the oven, allow them to cool slightly, and place them in the desiccator. Remember not to place the sample containers on a surface that can cause dirt or other foreign objects to adhere to the dishes.

Allow the sample containers to remain in the desiccator until completely cool. Remove from the desiccator and weigh the vessels.

The Total Dissolved Solids is calculated using the following equation:

$$TDS, mg/L = \frac{A - B}{V} \otimes 1000 mg/g$$

Where:
A = weight of sample residue and evaporating dish (g)
B = weight of evaporating dish (g)
V = volume of sample analyzed (L)

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank, one laboratory control sample, and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 100mL for porcelain dishes and 200mL for pre-weighed vessels of reagent water to serve as the blank matrix.

For the laboratory control sample, follow the procedures outlined above and use 50mL of the multi-analyte solids standard..

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 10:

Volatile Dissolved Solids (VDS) Procedures
EPA 160.4 and SM2540E

Preparation of Evaporating Dishes

Note that the same evaporating dishes will be used to determine the TDS and the VDS. The pre-weighed vessels may not be used for TDS if VDS is required.

Thoroughly clean the 100mL and 200mL evaporating dishes that will be required for the determination of VDS. It may be necessary to place Nochromix in the dish for a short time to remove dissolved solids from a previous analysis.

Rinse the evaporating dishes thoroughly with reagent water and allow them to dry. The dishes should be placed in the oven at 180°C to facilitate the drying.

Remove the evaporating dishes from the oven and place them in the muffle furnace. Turn on the muffle furnace, and elevate the temperature 100°C per hour until it reaches 550°C ± 50°C.

After the evaporating dishes have remained in the muffle furnace at 550°C ± 50°C for a minimum of one hour, remove the dishes and place them in the desiccator. Do not seal the door of the desiccator completely until the dishes have cooled. After the evaporating dishes have cooled, close the door of the desiccator. The evaporating dishes may be stored in the desiccator until ready for use.

Note: If the evaporating dishes are placed into the desiccator while hot and the top or door is sealed, a vacuum may form as the dishes cool. The top or door may be difficult to open if this occurs. This can occur very readily after the evaporating dishes have been removed from the muffle furnace.

Note: VDS determinations (and their associated TDS determination) must be performed using tared evaporating dishes ONLY, as the pre-weighed vessels are not capable of withstanding temperatures of 550 °C ± 50°C and therefore are not approved for VDS methods.

Determination of Volatile Dissolved Solids

Determine the Total Dissolved Solids as described in Attachment 9. Use evaporating dishes that have been prepared as above.

Place the evaporating dishes in the muffle furnace. Turn on the muffle furnace, and elevate the temperature 100°C per hour until it reaches 550°C ± 50°C. Record the time, oven ID, thermometer ID and temperature that is corrected and uncorrected once the range of 550°C ± 50°C is reached in the TALS batch.

After the evaporating dishes have remained in the muffle furnace at 550°C ± 50°C for a minimum of one hour, remove the evaporating dishes from the muffle furnace and place

them on a non-reactive surface to cool. Record the time, temperature that is uncorrected and corrected in the TALs batch.
Caution: the dishes will be extremely hot when removed. Do not place them on a surface that will melt or ignite

Note: One option is to turn the muffle furnace off and let then dishes cool in the furnace. After the dishes have cooled, place them in desiccator for at least one hour or overnight.

Remove the dishes from the desiccator and weigh the dishes to constant weight using the procedure outlined in Attachment 14.

The Volatile Dissolved Solids is calculated:

$$Volatile\ \ dissolved\ \ solids,\ mg/L = \frac{R_{180}\ -\ R_{550}}{V} \otimes 1000 mg/g$$

Where:
R_{180} = (weight of sample residue + evaporating dish @ 180°C)g - (evaporating dish weight)g = residue at 180°C (g)
R_{550} = (weight of residue + evaporating dish @ 550°C)g - (weight of evaporating dish)g = residue at 550°C (g)
V = volume of sample analyzed

QC Sample Preparation and Analysis
For each batch of 20 or fewer samples prepare a minimum of one method blank and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 100mL of reagent water for porcelain dishes to serve as the blank matrix.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or one sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 11:

Settleable Solids Procedures
EPA 160.5 and SM2540F

Sample Preparation and Analysis

Remove the samples from the refrigerator and allow them to come to room temperature.

Rinse the Imhoff cone well with reagent water. Wash with detergent, if needed.

Place the Imhoff cone in the holder and pour 1L of sample into the cone.

Allow the sample to settle for 45 minutes, using a NIST-traceable timer to measure elapsed time. Stir the sample gently with a glass rod to free matter stuck to the sides of the Imhoff cone.

Allow the sample to settle an additional 15 minutes, again using a NIST-traceable timer to measure elapsed time. Read the volume of settleable matter and report the results in mL/L. If less than 0.1mL of material has settled in the bottom, report the result as <0.1mL/L.

Ensure the following items are captured in the Batch Information screen in TALS:
Timer ID
Imhoff Cone ID
First Start Time
First End Time
Second start Time
Second End Time

For some samples a separation of settleable and floating materials will occur. In these instances, the volume attributed to the floating materials is not included in the determination of the final result.

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 1L of reagent water to serve as the blank matrix.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 12:

Percent Moisture and Total Solids Procedures SM2540G

Preparation of the Evaporating Dishes or Crucibles

Thoroughly clean the evaporating dishes or crucibles that will be required for the determination of total solids. It may be necessary to place Nochromix in the dish for a short time to remove dissolved solids from a previous analysis.

Rinse the evaporating dishes or crucibles thoroughly with reagent water and allow them to dry. The dishes should be placed in muffle furnace to facilitate the drying.

After the evaporating dish has remained in the muffle furnace for a minimum of two hours, remove the dishes from the oven and place in the desiccator. Do not close the door of the desiccator completely until the dishes have cooled. After the dishes have cooled, close the door of the desiccator. The evaporating dishes and crucibles may be stored in the desiccator until ready for use.

Note: If the dishes are placed into the desiccator while hot and the door is sealed, a vacuum may form as the dishes cool. If this occurs, the door of the desiccator may be difficult to open.

Determination of Total Solids (or Percent Moisture)

Calibrate and verify that the top loading balance is working within the proper parameters in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*.

Label the drying dish with an identification number.

Measure the weight of the pre-labeled, pre-cleaned dishes to the nearest 0.1mg on an analytical balance. Record this information as the tare weight in the analytical balance.

Thoroughly mix the sample with a stainless steel spatula or glass rod. It is important to obtain a homogeneous mixture prior to sub-sampling so that the sub-sample will accurately reflect the composition of the sample. Leaves, rocks, and other foreign materials should not be included in the sub-sample.

Note: If there is any doubt as to how to treat a given sample, contact the department manager to determine the proper course of action. SOP SA-QA-015*: Homogenization, Compositing, and Segregation of Samples* provides guidance for homogenizing samples.

Add approximately a 25-50g aliquot of the well-mixed sample to the dish. Record the weight to the nearest 0.1mg in the analytical balance.

Place the sample in the drying oven, maintained at 103°C -105° for at least 12 hours (overnight).

Remove the evaporation dishes from the oven, allow them to cool slightly, and place them in the desiccator. Remember not to place the evaporating dishes on a surface that can cause dirt or other foreign objects to adhere to the dishes.

Allow the evaporating dishes to remain in the desiccator until completely cool.

Remove the dishes from the desiccator and weigh the dishes to constant weight using the procedure outlined in Attachment 14.

The Percent Solids is calculated using the following equation:

$$percent_total_solids = \frac{A - B}{W} x\,100$$

Where:
A = weight of sample residue and evaporating dish (g)
B = weight of evaporating dish (g)
W = weight of sample used to determine the total solids (g)
i.e., W = weight $_{wetsample + dish}$ – weight$_{dish}$

The Percent Moisture is calculated using the following equation:

$$percent_moisture = \frac{W - (A - B)}{W} x\,100$$

Where:
A = weight of sample residue and evaporating dish (g)
B = weight of evaporating dish (g)
W = weight of sample used to determine the total solids (g)
i.e., W = weight $_{wetsample + dish}$ – weight$_{dish}$

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 10g of Ottawa Sand that has been prepared for metals analysis to serve as the blank matrix.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 13:
Volatile Solids, Ash Content, and Fixed Solids Procedures
SM2540G

Preparation of the Evaporating Dishes and Crucibles

Note that the same evaporating dishes will be used to determine the % moisture and total solids.

Thoroughly clean the evaporating dishes or crucibles that will be required for the determination of ash content and fixed solids. It may be necessary to place Nochromix in the dish for a short time to remove dissolved solids from a previous analysis.

Rinse the evaporating dishes thoroughly with reagent water and allow them to dry. The dishes should be placed in the oven at 105°C to facilitate the drying.

Remove the evaporating dishes from the oven and place them in the muffle furnace. Turn on the muffle furnace, and elevate the temperature 100°C per hour until it reaches 550°C ± 50°C.

After the evaporating dishes have remained in the muffle furnace at 550°C ± 50°C for a minimum of one hour, remove the dishes and place them in the desiccator. Do not seal the door of the desiccator completely until the dishes have cooled. After the evaporating dishes have cooled, close the door of the desiccator. The evaporating dishes may be stored in the desiccator until ready for use.

Note: If the evaporating dishes are placed into the desiccator while hot and the top or door is sealed, a vacuum may form as the dishes cool. The top or door may be difficult to open if this occurs. This can occur very readily after the evaporating dishes have been removed from the muffle furnace.

Determination of Volatile Solids, Ash Content, and Fixed Solids

Determine Percent Moisture, Total Solids (2540G) as described in Attachment 13. Use evaporating dishes that have been prepared as above.

Place the evaporating dishes in the muffle furnace. Turn on the muffle furnace, and elevate the temperature 100°C per hour until it reaches 550°C ± 50°C.

After the evaporating dishes have remained in the muffle furnace at 550°C ± 50°C for a minimum of one hour, remove the evaporating dishes from the muffle furnace and place them on a non-reactive surface to cool. Caution: the dishes will be extremely hot when removed. Do not place them on a surface that will melt or ignite

Note: One option is to turn the muffle furnace off and let then dishes cool in the furnace.

After the dishes have cooled, place them in desiccator for at least one hour or overnight.

Remove the dishes from the desiccator and weigh the dishes to constant weight using the procedure outlined in Attachment 14.

The Ash Content is calculated using the following equation:

$$percent_ash = \frac{A}{B} x\,100$$

Where:
A = weight of sample residue after heating to 550°C (g)
B = weight of sample residue after heating to 105°C (g)

The Ash content can also be reported as % Fixed Solids

The Volatile Solids is calculated using the following equation:

$$percent_volatile_solids = \frac{B - A}{B} x\,100$$

Where:
A = weight of sample residue after heating to 550°C (g)
B = weight of sample residue after heating to 105°C (g)

QC Sample Preparation and Analysis

For each batch of 20 or fewer samples prepare a minimum of one method blank and two separate sample duplicates.

For the method blank, follow the procedures outlined above and use 10g of Ottawa Sand that has been prepared for metals analysis to serve as the blank matrix.

For the sample duplicate sample, follow the procedures outlined above and prepare and analyze one sample in duplicate per batch or 1 sample in duplicate for every 10 samples analyzed, whichever is greater.

Attachment 14:

Constant Weight Determination Procedures

For all residue determinations except percent solids/moisture, the constant weight must be achieved. To verify constant weight has been achieved, replicate weighings of each sample must occur. Each sample must be placed back into the oven at the appropriate temperature and re-weighed after a minimum of 1 hour.

If the percent difference between the initial and subsequent weighing is less than 4% or the difference is less than 0.5mg from the previous weighing, the sample has been dried to a constant weight, and no further drying time is needed.

If the percent difference is greater than 4%, or if the difference is greater than 0.5mg, the sample must be dried and re-weighed until the “constant weight” criteria are achieved.

An NCM must be generated if constant weight cannot be achieved after a third weighing is performed.

Note: The “percent difference” and “difference” limits are separate criteria. Only one has to be met. The difference criteria will apply to low concentration samples and the percent difference criteria to higher concentration samples.

Note: When utilizing pre-weighed vessels, ensure a static-free environment when performing weigh-backs by using the De-ionizing U-Electrode in conjunction with the analytical balance. To ensure that the vessel is centered on the analytic balance platform, always use the weighing bracket.

Attachment 15:

Percent Solids/Moisture Procedures (Used for Dry Weight Correction) EPA 3500B, EPA 3500C, EPA 3550B, and EPA 3550C

Determination of Percent Solids (or Percent Moisture)

Calibrate and verify that the top loading balance is working within the proper parameters in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use)*.

Label an aluminum pan with an identification number. Create a new Moisture Batch in Analyst Desktop in TALS and enter the TALS IDs of the samples to be tested. Weigh the pan on the top loading balance. Record the weight (to the nearest 0.01g) of the aluminum pan in the column labeled "DishWeight" in the row of the corresponding sample.
****** Do NOT TARE the balance after weighing the dish.

Thoroughly mix the sample with a stainless steel spatula or glass rod. It is important to obtain a homogeneous mixture prior to sub-sampling so that the sub-sample will accurately reflect the composition of the sample. Leaves, rocks, and other foreign materials should not be included in the sub-sample.

Note: If there is any doubt as to how to treat a given sample, contact the department manager to determine the proper course of action. SOP SA-QA-015: Homogenization, *Compositing, and Segregation of Samples* provides guidance for homogenizing samples.

Add approximately a 10g aliquot of the well-mixed sample to the un-tared aluminum pan. The amount can vary by as much as +/- 50%. Record the weight to the nearest 0.01g in the column labeled "SampleMassWet."

Place the sample in the drying oven, maintained at 105°C +/- 5°C, for a minimum of 4 hours for % solids used for DW determination.

Remove the aluminum pan from the oven and allow to cool. Remember not to place the aluminum pan on a surface that can cause dirt or other foreign objects to adhere to the pan. Ensure that the surface that the pan is placed on can handle the temperature of the aluminum pan without damage.

Weigh the aluminum pan containing the sample residue on the top-loading balance and record the weight to the nearest 0.01g in the column labeled "SampleMassDry."

The TALS program automatically calculates the results for Percent Solids according to the equations listed below.

Use the following equation to calculate the Percent Solids:

$$Percent\ Solids = \frac{A - B}{C - D}\ x\ 100$$

Where:
A = weight of dry sample and aluminum pan
B = weight of aluminum pan
C = weight of wet sample and aluminum pan
D = weight of aluminum pan

Use the following equation to express the percent solids as a decimal equivalent ("Solids") for calculating sample results on a "dry weight basis":

$$\text{Solids} = \frac{\text{Percent Solids}}{100},$$

Or

$$Solids = \frac{A - B}{C - D}$$

Where:
A = weight of dry sample and aluminum pan
B = weight of aluminum pan
C = weight of wet sample and aluminum pan
D = weight of aluminum pan

Use the following equation to express the percent solids as percent moisture:

$$\text{Percent Moisture} = 100 - \text{Percent Solids}$$

Attachment 16:
Labware Cleaning Procedures

The graduated cylinder used for measuring initial sample volumes must be rinsed three times with reagent water between samples. Additionally, each day all non-disposable apparatus must be cleaned as outlined below:

GLASSWARE CLEANING PROCEDURES - GENERAL LAB

MISCELLANEOUS APPARATUS

1. Scrub with hot tap water and Liquinox.
2. Rinse thoroughly with tap water.
3. Rinse at least three times with DI water.
4. Air-dry and store inverted in a cabinet or capped.

NOTE:

1. Do not use soap for cleaning COD digestion tubes.
2. Burets may be cleaned by filling with 10% KOH in methanol, allowing to stand for one hour, then rinsing thoroughly with DI water.
3. Evaporating dishes used for TDS determinations are cleaned by rinsing thoroughly with tap water, soaking for several hours in Nochromix, rinsing thoroughly with tap water, and rinsing three times with DI water. The dishes are then oven-dried.

TKN / TOTAL-P DIGESTION TUBES

1. Scrub with hot tap water and Liquinox.
2. Rinse thoroughly with tap water.
3. Rinse once with Nochromix.
4. Rinse at least three times with DI water.

CYANIDE DISTILLATION APPARATUS

1. Scrub with hot tap water and Liquinox.
2. Rinse thoroughly with tap water.
3. Rinse with 10% nitric acid, being certain to force at least 10mL through each dispersion tube.
4. Rinse thoroughly with DI water.

ODOR-FREE GLASSWARE

1. Scrub with hot tap water and Liquinox.
2. Rinse with acid cleaning solution.
3. Rinse thoroughly with odor-free water.
4. Glassware used in odor testing should be reserved for that purpose only.

FGE003:08.17.18:2

Revision History

Summary of Changes Revision 12B:

- Updated Equipment Listing with current ovens utilized in the laboratory. ANAB Audit 2020.

Summary of Changes Revision 12A:

- Section 2.5 and Attachment 9 have been updated with oven conditions for the evaporation of TDS samples. Samples will be evaporated at 115-125C. ANAB Audit 2020
- Added Portable Conductivity Meter to Section 6.1.
- Updated section 7.3 with current standards utilized.
- Section 9.1 the LCS as a default QC item for EPA160.4 and SM2540E was removed.
- Added comments to section 9.3 that an NCM must be generated if constant weight is not achieved after three weighing.
- Updated disposal of soil material in section 14.1
- Removed the LCS and LCSD criteria in Attachment 3 for method EPA160.4, SM2540E and SM2540G.
- Removed use of PC titrate to measure conductivity in Attachment 5 and 9. The laboratory uses a portable conductivity meter which is calibrated each day of use.
- Removed prep of filters from Attachment 7 and Attachment 8. The lab purchased pre-certified filters for TSS and VSS.
- Updated Attachment 9 for TDS residue criteria. Sample must be reanalyzed if a minimum residue of 2.5mg is not achieved and less than 200mL of sample was utilized. An NCM must be initiated if a minimum residue of 2.5gm was not achieved when utilizing the volume of 200mL of sample. ANAB Audit 2020

Summary of Changes from Previous Revision 12:

- Updated SOP signatories to reflect current responsibilities and titles.
- Added part numbers for ProWeigh Double filters used for TSS and VSS analysis.
- Section 9.2- removed requirement for QA to login filter check for TSS. The ProWeigh Double filters utilized by the laboratory are tested for suitability by the vendor.
- Updated company name and logo where applicable.

MERCURY PREPARATION AND ANALYSIS

1.0 Scope and Application

This SOP gives the procedures for the determination of mercury by cold vapor atomic absorption spectrophotometry (CVAA). The routine matrices performed by this procedure are waters and soils; however, this procedure may be adapted to accommodate other matrices as outlined in Section 16.1.

The reporting limits (RL), the method detection limits (MDL), and the accuracy and precision criteria associated with this procedure are provided in the TALS Method Limit Groups (MLGs).

This SOP was written by and for Eurofins TestAmerica's Savannah laboratory.

2.0 Summary of Method

This procedure is based on the absorption of characteristic radiation at 253.7nm by mercury vapor. Samples are digested with acids and potassium permanganate via the hot block digestion procedure. Upon analysis, the instrument introduces stannous chloride to the digestate to convert all forms of mercury to the same oxidation state. The mercury is then aerated from solution after passing through a mixing coil. The mixture passes through a gas/liquid separator and through a drying tube. The vapor is passed through a flow cell positioned in the light path of an atomic absorption spectrophotometer. Mercury concentration is measured as a function of absorbance.

This SOP is based on the following methods: EPA 7470A (liquids), EPA 7471B (solids), and EPA 245.1.

3.0 Definitions

Refer to the Glossary Section of the *Quality Assurance Manual* (QAM) for a complete listing of applicable definitions and acronyms.

4.0 Interferences

4.1 Procedural Interferences

4.1.1 Interferences may be caused by contaminants in solvents, reagents, glassware, and other sample processing apparatus and can make identification and/or quantification of the target analytes difficult.

4.1.2 All sample collection containers are single-use disposable containers which limits the potential for contamination. All non-disposable labware must be scrupulously cleaned in accordance with the posted Labware Cleaning Instructions to ensure it is free from contaminants and does not contribute artifacts.

4.1.3 High purity reagents and solvents are used to help minimize interference problems. Hydrochloric acid, nitric acid, and sulfuric acid must be verified prior to use in accordance with the Eurofins TestAmerica Solvent Lot Testing Program.

4.1.4 Instrument and/or method blanks are routinely used to demonstrate all reagents and apparatus are free from interferences under the conditions of the analysis.

4.2 Matrix Interferences

4.2.1 Matrix interferences may be caused by contaminants that are co-extracted from the sample matrix. The sample may require cleanup or dilution prior to analysis to reduce or eliminate the interferences.

4.2.2 Interfering contamination may occur when a sample containing low concentrations of analytes is analyzed immediately following a sample containing relatively high concentrations of analytes. As such, samples known to be clean should be analyzed first. To prevent carryover into subsequent samples, analysis of reagent blanks may be needed after the analysis of a sample containing high concentrations of analytes.

4.2.3 Potassium permanganate is added to eliminate the possibility of interference from sulfide and certain organic compounds.

4.2.4 High levels of residual chlorine (such as those produced when seawaters, brines, and industrial effluents high in chlorides are digested) are known to interfere with this analysis. Addition of extra potassium permanganate may be needed during the digestion of samples containing chloride. Also, the samples are not capped tightly during digestion so that excess chlorine can escape.

4.2.5 Interferences have been reported for waters containing sulfide, chloride, copper and tellurium. Organic compounds which have broad band UV absorbance (around 253.7 nm) are confirmed interferences. The concentration levels for interferents are difficult to define. This suggests that quality control procedures must be strictly followed.

4.2.6 Volatile materials (e.g., chlorine) which absorb at 253.7 nm will cause a positive interference. In order to remove any interfering volatile materials, the dead air space in the digestion vessel should be purged before addition of stannous chloride solution.

5.0 Safety

Employees must abide by the policies and procedures in the Eurofins TestAmerica Environmental Health and Safety Manual (EHSM), the Eurofins TestAmerica Savannah Addendum to the EHSM, and this document.

This procedure may involve hazardous materials, operations, and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user to follow appropriate safety, waste disposal, and health practices under the assumption that all samples and reagents are potentially hazardous.

The analyst must protect himself/herself from exposure to the sample matrix. Many of the samples that are tested may contain hazardous chemical compounds or biological organisms. The analyst must, at a minimum, wear protective clothing (lab coat), eye protection (safety glasses or face shield), disposable latex or nitrile gloves, and closed-toe, nonabsorbent shoes when handling samples.

5.1 Specific Safety Concerns or Requirements

Nitric and hydrochloric acids are extremely hazardous as oxidizers, corrosives, poisons, and are reactive. Inhalation of the vapors can cause coughing, choking, irritation of the nose, throat, and respiratory tract, breathing difficulties, and lead to pneumonia and pulmonary edema. Contact with the skin can cause severe burns, redness, and pain. Nitric acid can cause deep ulcers, and staining of the skin to a yellow or yellow-brown color. These acid vapors are irritating and can cause damage to the eyes. Contact with the eyes can cause permanent damage.

Sulfuric acid is a strong oxidizer and is a corrosive. It will react violently when combined with organic compounds, possibly producing fire. Inhalation can cause irritation of the nose, throat, mucus membranes, and upper respiratory tract. Contact with the eyes can cause blurred vision, redness, pain, and even blindness.

Samples that contain high concentrations of carbonates or organic matter, or samples that are at elevated pH can react violently when acids are added. Acids must be added to samples under a hood to avoid splash/splatter hazards and/or possibly toxic vapors that will be given off when the samples are acidified.

The making of aqua regia can produce toxic fumes and heat. This procedure must be performed under a fume hood.

The exhaust of the mercury analyzer must be vented or trapped so that mercury vapors do not enter the laboratory.

The preparation of the samples for mercury analysis uses a hot-block with a temperature of ~95ºC. The water and the steam produced can cause burns to unprotected skin. Employees must use appropriate PPE when working with sample digestions.

Mercury compounds are highly toxic if swallowed, inhaled, or absorbed through the skin. Analyses should be conducted in a laboratory exhaust hood. The analyst should use chemical resistant gloves when handling concentrated mercury standards.

The acidification of samples containing reactive materials may result in the release of toxic gases, such as cyanides or sulfides. Acidification of samples should be done in a fume hood.

5.2 Primary Materials Used

The following is a list of the materials used in this procedure, which have a serious or significant hazard rating, and a summary of the primary hazards listed in their MSDS/SDS.

NOTE: This list does not include all materials used in the procedure. A complete list of materials used in this procedure can be found in the Reagents and Standards Section and the Equipment and Supplies Section of this SOP.

Employees must review the information in the MSDS/SDS for each material before using it for the first time or when there are major changes to the MSDS/SDS. Electronic copies of MSDS/SDS can be found using the "MSDS" link on the Oasis homepage or on the EH&S webpage on Oasis.

Material	Hazards	Exposure Limit[1]	Signs and Symptoms of Exposure
Sulfuric Acid[2]	Corrosive Oxidizer Dehydrator Poison	1mg/m^3 TWA	Inhalation produces damaging effects on the mucous membranes and upper respiratory tract. Symptoms may include irritation of the nose and throat, and labored breathing. Symptoms of redness, pain, and severe burn can occur. Contact can cause blurred vision, redness, pain and severe tissue burns. Can cause blindness.
Nitric Acid[2]	Corrosive Oxidizer Poison	2ppm TWA 4ppm STEL	Nitric acid is extremely hazardous; it is corrosive, reactive, an oxidizer, and a poison. Inhalation of vapors can cause breathing difficulties and lead to pneumonia and pulmonary edema, which may be fatal. Other symptoms may include coughing, choking, and irritation of the nose, throat, and respiratory tract. Can cause redness, pain, and severe skin burns. Concentrated solutions cause deep ulcers and stain skin a yellow or yellow-brown color. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Hydrochloric Acid[2]	Corrosive Poison	5ppm Ceiling	Inhalation of vapors can cause coughing, choking, inflammation of the nose, throat, and upper respiratory tract, and in severe cases, pulmonary edema, circulatory failure, and death. Can cause redness, pain, and severe skin burns. Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.

Material	Hazards	Exposure Limit[1]	Signs and Symptoms of Exposure
Potassium Permanganate	Oxidizer	5mg/m^3 for Mn Compounds	Causes irritation to the respiratory tract. Symptoms may include coughing, shortness of breath. Dry crystals and concentrated solutions are caustic, causing redness, pain, severe burns, brown stains in the contact area and possible hardening of outer skin layer. Diluted solutions are only mildly irritating to the skin. Eye contact with crystals (dusts) and concentrated solutions causes severe irritation, redness, and blurred vision and can cause severe damage, possibly permanent.
Potassium Persulfate	Oxidizer	None	Causes irritation to the respiratory tract. Symptoms may include coughing, shortness of breath. Causes irritation to skin and eyes. Symptoms include redness, itching, and pain. May cause dermatitis, burns, and moderate skin necrosis.
[1]Exposure limit refers to the OSHA regulatory exposure limit.			
[2]Always add acid to water to prevent violent reactions.			

6.0 Equipment and Supplies

6.1 Equipment and Instrumentation

Top-loading Balance – Verify in accordance with SOP SA-AN-100: *Laboratory Support Equipment: Verification and Use*

Thermometers – Verify in accordance with SOP SA-AN-100: *Laboratory Support Equipment: Verification and Use*

Water bath or heating block capable of maintaining temperature of 95 ± 3°C

Leeman Hydra AA or other suitable automated mercury analyzer

Mercury Hollow Cathode Lamp

Absorption Cell

Nitrogen or argon gas supply and appropriate fittings

Air Pump

Pump (Aeration) tubing of appropriate sizes for use on the Hydra AA

Drying Tube – Purchased pre-packed from Leeman Labs

6.2 Analytical Data System / Software / Hardware

The Leeman software is used on a Windows-based PC to schedule and acquire data. The raw data from the Hg Analyzer is manually checked for validity by a minimum of 2 analysts. Raw instrument data are uploaded to the laboratory's LIMS (i.e., TALS) via the Environmental Information Systems Corporation Metals Analytical Review. Additionally, any quality control failures are flagged in TALS, as appropriate.
The QA department maintains a Master Equipment Listing which documents to Firmware and/or Software utilized by the instrumentation.

6.3 Volumetric Containers and Dispensers

All volumetric labware must be verified in accordance with SOP SA-AN-100: *Laboratory Support Equipment (Verification and Use).* Refer to Attachment 6 for Labware Cleaning Procedures.

Volumetric Labware	Volume	Type (Quantitative / Qualitative)	Use	Verification Frequency	Laboratory Verification Criteria
Disposable Medicine Cups	10mL	Qualitative	Used to contain sample aliquot for pH measurement	None	None
Autosampler Vials	10mL	Qualitative	Holding sample on instrument	None	None
Digitube Disposable Digestion Vials (Class A)	100mL	QUANTITATIVE	Preparing Digestions, Determination of Initial and Final Volumes	None, if received w/ COA	None, if received w/ COA
Eppendorf-Style Mechanical Pipettes	Various	QUANTITATIVE	Preparing Dilutions, Standard and Reagent Preparation and Spiking	Prior to 1st use, then quarterly thereafter (Daily for DOD)	Accuracy = 2% Precision = 1%
Glass Volumetric Flasks (Class A)	2L	QUANTITATIVE	Reagent Preparation	None (Class A)	None (Class A)
Glass Beakers (Class A)	2L	QUANTITATIVE	Reagent Preparation	None (Class A)	None (Class A)
Glass Disposable Pipettes	5mL	Qualitative	Preparing Dilutions, Standard and Reagent Preparation and Spiking	Per Lot	Accuracy = 2% Precision = 1%
Pump-Style Mechanical Pipettes	Various	QUANTITATIVE	To deliver acids/bases for pH adjustments	Prior to 1st use, then quarterly thereafter (Daily for DOD)	Accuracy = 2% Precision = 1%

6.3 Lab Supplies

pH paper

6.4 Sample Collection Containers

All sample collection containers are single-use disposable containers which limits the potential for contamination.

The routine sample collection containers supplied by the laboratory are:

Waters or Field-Filtered Dissolved Mercury Samples:
250mL plastic, nitric acid – purchased with Certificate of Analysis attesting to purity.

Soil Samples:
4oz plastic soil jar, unpreserved – purchased with Certificate of Analysis attesting to purity.

Wipe Samples:
40mL VOA vial, Acetic acid in water, pH 4.93 +/- 0.05 – purchased with Certificate of Analysis attesting to purity.

Leachate Samples (originally aqueous):
1L amber glass, unpreserved – purchased with Certificate of Analysis attesting to purity.

Leachate Samples (originally solid):
16oz glass soil jar, unpreserved – purchased with Certificate of Analysis attesting to purity.

Lab-Filtered Dissolved Mercury Samples
250mL plastic, unpreserved – purchased with Certificate of Analysis attesting to purity.

7.0 Reagents and Standards

The standards and reagents listed are those in use at the time this SOP was updated. Other standard and reagent stocks, vendors, and concentrations may be used provided they are fully documented and in compliance with method requirements.

7.1 Expiration Dates

Expiration dates (time from initial use or receipt to final use) for standard and reagent materials must be set according to the guidance in this SOP. Note: These are maximum expiration dates and are not to be considered an absolute guarantee of standard or reagent quality. Sound judgment must be used when deciding whether to use a standard or reagent. If there is doubt about the quality of a standard or reagent material, a new material must be obtained or the standard or reagent material verified. Data quality must not be compromised to extend a standard's life.

The expiration date of any standard or reagent must not exceed the expiration date of the standard or reagent that was used to prepare it.

7.2 Reagents

Reagents must be prepared and documented in accordance with SOP SA-AN-041: *Reagent and Standard Materials Procedures.*

Hydrochloric acid, nitric acid, and sulfuric acid must be verified prior to use in accordance with the Eurofins TestAmerica Solvent Lot Testing Program.

7.2.1 Blank Matrix – Teflon Chips, Ottawa Sand, or other suitable matrix. Used for the preparation of soil QC samples.

7.2.2 Laboratory Reagent Water – ASTM Type II

7.2.3 Nitric Acid (HNO_3), concentrated, reagent grade – stable under ordinary conditions of use and storage
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration:
Unopened: Manufacturer's expiration date
Opened: 5 years from date opened

7.2.4 Hydrochloric Acid (HCl), concentrated-reagent grade – stable under ordinary conditions of use and storage
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration:
Unopened: Manufacturer's expiration date.
Opened: 5 years from date opened

7.2.5 Aqua Regia (1:1): To 4 volumes of reagent water, carefully add 3 volumes of concentrated HCl and 1 volume of concentrated HNO3. Store this reagent away from incompatibles, combustibles, organics, and other readily oxidizable materials. This reagent will be stable for up to 3 months.

Note: This reagent must be prepared under a fume hood.

7.2.6 Potassium permanganate ($KMnO_4$), mercury free – stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Keep away from heat and avoid storage on wood floors. Store away from incompatibles, combustibles, organics and other readily oxidizable materials.

Expiration:
Unopened: Manufacturer's expiration date
Opened: 5 years from date opened

7.2.7 Potassium permanganate, mercury-free, 5% solution (w/v) – Dissolve 50g of $KMnO_4$ in 1000mL of reagent water. Stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Keep away from heat and avoid storage on wood floors. Store away from incompatibles, combustibles, organics and other readily oxidizable materials.
Expiration: 1 year from date prepared

7.2.8 Sodium Chloride (NaCl) – stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area.
Expiration:
Unopened: Manufacturer's expiration date
Opened: 5 years from date opened

7.2.9 Hydroxylamine Sulfate ($(NH_2OH)•2H_2O$) – stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Store away from incompatible materials.
Expiration:
Unopened: Manufacturer's expiration date
Opened: 5 years from date opened

7.2.10 Sodium chloride hydroxylamine sulfate solution – Dissolve 120g NaCl and 120g hydroxylamine sulfate in reagent water in a 1-L volumetric flask and dilute to volume. Stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Store away from incompatible materials.
Expiration: 1 year from date prepared

7.2.11 Potassium persulfate ($K_2S_2O_8$) – stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Keep away from heat and avoid storage on wood floors. Store away from incompatibles, combustibles, organics and other readily oxidizable materials.
Expiration:
Unopened: Manufacturer's expiration date
Opened: 5 years from date opened

7.2.12 Potassium persulfate, 5% solution (w/v) – Dissolve 50g potassium persulfate in 1000mL reagent water. Stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Keep away from heat and avoid storage on wood floors. Store away from incompatibles, combustibles, organics and other readily oxidizable materials.
Expiration: 1 year from date prepared

7.2.13 Rinse Water, 5% HCl / 1%HNO_3 – to a clean 2-L bottle, add 1-L of reagent water. Carefully add 100mL of concentrated hydrochloric acid. Carefully add 20mL of concentrated nitric acid. Dilute to a final volume of 2L. Other volumes may be utilized providing the reagent proportions remain the same. Stable under ordinary conditions of use and storage.

Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration: 1 year from date prepared

7.2.14 Stannous chloride ($SnCl_2.2H_2O$) – reagent grade, suitable for mercury determination. Stable if stored in tightly closed containers.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Keep away from incompatible materials. It will absorb air and form the insoluble oxychloride.
Expiration:
Unopened: Manufacturer's expiration date
Opened: 5 years from date opened

7.2.15 Stannous chloride ($SnCl_2•2H_2O$) solution – to a clean 2L volumetric flask, add 100g of stannous chloride. Add approximately 400mL of reagent water. Carefully add 500mL of concentrated hydrochloric acid. Add a stirring bar, and stir on a stir plate until the stannous chloride is dissolved. Remove the stirring bar and dilute to volume with reagent water. Stable under ordinary conditions of use and storage.
Storage: Store in a tightly closed container in a cool, dry, ventilated area. Keep away from incompatible materials.
Expiration: 1 year from date prepared

7.2.16 Sulfuric Acid (H_2SO_4), concentrated reagent grade – stable under ordinary conditions of use and storage.
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration:
Unopened: Manufacturer's expiration date
Opened: 5 years from date opened

7.2.17 Nitric Acid (HNO_3), 1:1 – Slowly add 250mL of concentrated nitric acid to 250mL of laboratory reagent water in a 1-L beaker. Mix well and transfer to a tightly closed container.
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration: 2 years from date prepared

7.3 Standards

Standards must be prepared and documented in accordance with SOP SA-AN-041: *Reagent and Standard Materials Procedures.* Certificates of analysis or purity must be received with all purchased standards, and attached to TALS.

7.3.1 Hg Stock Standard, 1000mg/L – currently purchased from SPEX.
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration: Stable under ordinary conditions of use and storage up to the manufacturer's expiration date.

7.3.2 Second Source Hg Stock Standard, 1000mg/L – currently purchased from Environmental Express.
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration: Stable under ordinary conditions of use and storage up to the manufacturer's expiration date.

7.3.3 Calibration Standards

7.3.3.1 Mercury Intermediate Standard, 500ug/L – Add 0.050mL of the purchased 1000mg/L Hg Stock Standard and 2.5mL of nitric acid to about 50mL of reagent water in a 100-mL volumetric flask and dilute to volume with reagent water.
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration: Stable under ordinary conditions of use and storage for up to 28 days. The expiration date cannot exceed the expiration of any of the components.

7.3.3.2 Mercury Calibration Standards – Prepare ICAL daily according to the matrix given in the instructions below:

Waters:
- Transfer 0.0, 0.02, 0.04, 0.1, 0.3, and 0.5mL portions of the Mercury Intermediate Standard to a series of 100mL disposable vials.
- Add reagent water from a graduated cylinder to each vial to make a final volume of 50mL. This results in calibration standard concentrations of 0.0, 0.2, 0.4, 1.0, 3.0, and 5.0ug/L mercury.
- Mix well. Digest according to the procedures in Section 10.1.1.

Soils:
- Add 0.50g blank matrix and 5.0mL to each of six 100mL disposable vials.
- Transfer 0.0, 0.02, 0.04, 0.1, 0.3, and 0.5mL portions of the Mercury Intermediate Standard to the vials.
- This results in calibration standard concentrations of 0.0, 0.020, 0.040, 0.10, 0.30, and 0.50mg/kg mercury.
- Digest according to the procedures in Section 10.1.2, omitting the initial addition of 5mL of water.

7.3.4 Initial Calibration Verification Standards (also used as QCS and IPC standards)

7.3.4.1 Second Source Intermediate Standard, 1.0mg/L – Add 0.1mL of the 1000mg/L Second Source Hg Stock Standard, and 2.5mL of nitric acid to about 50mL of reagent water in a 100mL volumetric flask and dilute to volume with reagent water.
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration: Stable under ordinary conditions of use and storage for up to 28 days. The expiration date cannot exceed the expiration date of any of the components.

7.3.4.2 Second Source Initial Calibration Verification (ICV) Standard, 3.0ug/L – Add 0.15mL of the 1.0mg/L Second Source Intermediate Standard to a 100mL disposable vial. Add enough reagent water from a graduated cylinder to give a final volume of 50mL. The ICV is now ready to be digested. Other final volumes may be used as long as the reagent ratios are kept the same.
Storage: Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Store away from sunlight, heat, water, and incompatible materials.
Expiration: Stable under ordinary conditions of use and storage for up to 28 days. The expiration date cannot exceed the expiration date of any of the components.

7.3.4.3 Continuing Calibration Verification (CCV) solution - Prepare CCV daily according to the matrix given in the instructions below:

Waters:

- Add 50mL of DI water to two 100-mL digestion vials.
- Add 0.25mL of the 500ug/L Hg Intermediate Standard to each vial and mix.
- Prepare in accordance with Section 10.1.1.

Soils:

- Add 0.25mL of the 500ug/L Hg Intermediate Standard to a 100-mL vial.
- Prepare in accordance with Section 10.1.2.

7.3.5 QC Standards

7.3.5.1 Analytical Spike Standard, 73.26ug/L – Using a graduated cylinder, add 20mL of the 500ug/L Hg Intermediate Standard, and 5.0mL of nitric acid to about 50mL of reagent water and dilute to 136.5mL final volume with reagent water. Note: Since this standard is not digested the volume has been adjusted to compensate for the dilution that the other standards and samples undergo during the digestions.

8.0 Sample Collection, Preservation, Shipment, and Storage

8.1 Aqueous Samples

8.1.1 Total Mercury

Aqueous samples are routinely collected in 250mL plastic containers containing 3mL of a 1:3 nitric acid preservative. The preservative should be sufficient to achieve a sample pH of less than 2. Follow the procedures in 8.1.3 for checking and recording the pH.

Although no temperature preservation is required, samples are routinely iced at the time of collection at 0-6°C (less than 6°C, but not frozen). Samples are stored at room temperature until the time of digestion. Samples must be digested and analyzed within 28 days of sample collection. Digestates are stored at room temperature until the time of analysis.

NCMs must be initiated for samples collected in improper containers and containing improper or insufficient preservatives.

8.1.2 Dissolved Mercury

Field Filtered
Aqueous samples for dissolved metals are routinely filtered at the time of sampling and collected in 250mL plastic containers containing 3mL of a 1:3 nitric acid preservative. The preservative should be sufficient to achieve a sample pH of less than 2. Check and record the pH as directed in Section 8.1.3.

Lab Filtered
If the sample is to be filtered in the laboratory, the sample must be collected in 250mL plastic container with no preservatives. The sample must be stored at 0-6°C (less than 6°C but not frozen) until filtered. Once filtered, the laboratory will add nitric acid to obtain a pH of less than 2.

Although no temperature preservation is required, samples are routinely iced at the time of collection at 0-6°C (less than 6°C but not frozen). Samples are stored at room temperature until the time of digestion. Samples must be digested and analyzed within 28 days of sample collection. Digestates are stored at room temperature until the time of analysis.

NCMs must be initiated for samples collected in improper containers and containing improper or insufficient preservatives.

8.1.3 Preservation Checks – pH Verification

Place a piece of pH paper in a disposable medicine cup.

Pour a few drops of sample into the medicine cup and note the color change of the pH paper. Record results on the preservation sheet.

If the pH<2, proceed with digestion and analysis.

If the pH is >2, adjust the sample pH to less than 2 using 1:1 nitric acid. Record the volume of acid needed to adjust the sample to <2 and initiate an NCM.

If the volume of acid needed to adjust the pH to <2 exceeds 1% of the volume of the container (2.5mL per 250mL container), stop and notify the supervisor.

If the sample is a “Rush” and the pH>2, notify the supervisor or project manager immediately.

Allow the sample to sit for 24 hours and re-check the pH. If pH<2, proceed with digestion and analysis. If pH >2, stop and contact the supervisor immediately

Note: To avoid cross-contamination, use a separate medicine cup and piece of pH paper per sample. Do not dip the pH paper into the sample container. The pH paper dye may bleed into the sample and affect sample results.

8.2 Soil Samples

Soil samples are routinely collected in 4oz plastic soil containers.

Samples must be iced at the time of collection and maintained at 0-6°C (less than 6°C but not frozen) until the time of digestion. Samples must be digested and analyzed within 28 days of collection. Digestates are stored at room temperature until the time of analysis.

9.0 Quality Control

SOP SA-QA-017: *Evaluation of Batch QC Data* and the SOP Summary in Attachment 3 provide requirements for evaluating QC data.

9.1 Batch QC

9.1.1 EPA 245.1 – Drinking Water

A digestion batch consists of up to 20 environmental samples and the associated QC items extracted together within a 24 hour period.

The laboratory's default minimum QC items performed for each digestion batch are: a method blank, a laboratory control sample (LCS), a low-level LCS (LLCS), a matrix spike (MS) to be performed on a minimum of 10% of samples or one per batch – whichever is greater, and a matrix spike duplicate (MSD).

This frequency equates to the following:

- For a batch of 10 or fewer samples, the minimum QC items are a method blank, an LCS, an LLCS, 1 matrix spike, and 1 matrix spike duplicate (MSD).
- For a batch of 11-20 samples, the minimum QC items are a method blank, an LCS, an LLCS, 1 matrix spike (from sample 1-10), another matrix spike (from sample 11-20), and a matrix spike duplicate (MSD).

Note: Unless the client has specified which sample to use as the matrix spike, the matrix spike must be selected at random from the samples in the batch. Field QC (e.g., equipment blanks, trip blanks, and field blanks) must not be used for MS/MSD unless specifically requested to do so by the client or unless there is insufficient sample available for performing MS/MSD using an actual field sample.

9.1.2 EPA 245.1 – Clean Water Act

A digestion batch consists of up to 20 environmental samples and the associated QC items extracted together within a 24 hour period.

The laboratory's default minimum QC items performed for each digestion batch are: a method blank and a laboratory control sample (LCS), a matrix spike (MS) to be performed on a minimum of 10% of samples or one per batch – whichever is greater, and a matrix spike duplicate (MSD).

This frequency equates to the following:

- For a batch of 10 or fewer samples, the minimum QC items are a method blank, an LCS, 1 matrix spike, and 1 matrix spike duplicate.
- For a batch of 11-20 samples, the minimum QC items are a method blank, an LCS, 1 matrix spike (from sample 1-10), another matrix spike (from sample 11-20), and a matrix spike duplicate.

9.1.3 EPA 7470A and EPA 7471B

A digestion batch consists of up to 20 environmental samples and the associated QC items. The laboratory's default minimum QC items performed for each digestion batch are: a method blank, a laboratory control sample (LCS), a matrix spike (MS), and a matrix spike duplicate (MSD).

The routine container supplied for this method is a 250mL (water) or 4oz (soil) container. 50mL or 1g is required for digestion. Reduced sample initial volumes or weights may be necessary to achieve the required batch QC frequency; however, the minimum digestion amount to be used is 10mL or 0.2g.

Note: Spike amounts must be adjusted to compensate for these reduced initial volumes or weights. Since final volumes are not easily reduced, elevated reporting limits will be provided when reduced initial volumes and weights are used

9.1.4 If there is insufficient sample volume to perform the required matrix spike(s), the LCS must be prepared in duplicate (i.e., LCS/LCSD). An NCM must be initiated on all affected samples to denote this situation. Insufficient sample volume or weight is defined as receiving less than a total of 50mL or 1g.

Note: If an LCS and LCSD are performed, both QC items must be evaluated and reported. Acceptable recoveries (as well as %RPD) for both LCS and LCSD are required.

9.1.5 Batch QC must meet the criteria given in Attachment 3 of this SOP.

9.2 Instrument QC

9.2.1 Initial Calibration (ICAL)

The instrument must be calibrated in accordance with SOP SA-QA-016: *Evaluation of Calibration Curves.* This SOP provides requirements for establishing the calibration curve and gives the applicable formulas.

Instrument calibration is performed by analyzing a series of known standards. The calibration curve must consist of a minimum of 5 standards and a blank. The lowest level calibration standard must be at or below the reporting limit, and the remaining standards will define the working range of the analytical system.

The initial calibration standards must be prepared daily for each sample matrix prepared on that day.

The initial calibration standard concentrations currently in use in the laboratory are as follows:

Standard Level	Water Concentration (ug/L)	Soil/Solid Concentration (mg/kg)
1	0.0	0.0
2	0.2	0.020
3	0.4	0.040
4	1.0	0.10
5	3.0	0.30
6	5.0	0.50

Refer to Section 7.3 for the standard preparation instructions. Other standard concentrations may be used provided they support the reporting limit and are fully documented in accordance with SOP SA-AN-041.

The correlation coefficient (r) of the regression curve must be greater than 0.995 for the initial calibration curve to be acceptable.

9.2.2 Second Source Initial Calibration Verification (ICV)

The calibration curve must be verified initially – prior to any sample analyses – in accordance with SOP SA-QA-016 with a standard obtained from a second source.

For EPA 245.1, the ICV must be within 5% of the true value to be acceptable.
For EPA 7470A and EPA 7471B, the ICV must be within 10% of the true value to be acceptable.

Note: The ICV is utilized to satisfy the EPA 245.1 requirement to analyze a QCS and IPC.

The initial calibration verification standard concentration currently in use in the laboratory is equivalent to level 5 of the ICAL. Refer to Section 7.3 for the standard preparation instructions. Another standard concentration may be used provided it is mid-level and fully documented in accordance with SOP SA-AN-041.

9.2.3 Initial Calibration Blank (ICB) / Continuing Calibration Blank (CCB)

The instrument must be shown to be free from contamination by the analysis of calibration blanks. Initial calibration blanks are analyzed immediately following the ICV. Continuing calibration blanks are analyzed immediately following each CCV.

The absolute value of the initial and continuing calibration blanks must be <½RL to be acceptable.

9.2.4 Continuing Calibration Verification

The initial calibration curve must be verified initially and after every 10 samples with a mid-level standard.

For EPA 245.1, all CCVs must be within 10% of the true value to be acceptable.
For EPA 7470A and EPA 7471B, all CCVs must be within 10% of the true value to be acceptable.

The continuing calibration verification standard concentration currently in use in the laboratory is equivalent to the mid-point of the calibration curve, or 2.5ug/L. Refer to Section 7.3 for the standard preparation instructions. Another standard concentration may be used provided it is mid-level and fully documented in accordance with SOP SA-AN-041.

Note: The CCV is utilized to satisfy the EPA 245.1 requirement to analyze an IPC.

9.2.5 Reporting Limit Standard

Certain project plans require the analysis of a reporting limit standard. If required, the reporting limit standard must be analyzed daily after the ICB, to verify the accuracy of the calibration curve at the reporting limit. The limits of recovery for the RL standard are 50-150%.

9.2.6 Quality Control Standard (QCS)

EPA 245.1 requires a second source QCS to be performed quarterly, at a minimum. The QCS must recover within 10% to be acceptable.

The laboratory uses the ICV to satisfy this QCS requirement.

9.2.7 Instrument Performance Check (IPC)

EPA 245.1 requires an IPC to be performed daily, after each calibration and after every tenth sample. The initial IPC must recover within 5% to be acceptable. Subsequent IPCs must recover within 10% to be acceptable.

The laboratory uses the ICV to satisfy the initial IPC requirement and the CCV to satisfy any subsequent IPC requirements.

9.3 Corrective Action for Out-of-Control Data

When the quality control parameters do not meet the criteria set forth in this SOP, corrective action must be taken in accordance with SOP SA-QA-005: *Preventive and Corrective Action Procedures* the QC Summary Table in Attachment 3. SOP SA-QA-005 provides contingencies for out-of-control data and gives guidance for exceptionally permitting departures from approved policies and procedures. Nonconformance Memos must be initiated to document all instances where QC criteria are not met and all departures from approved policies and procedures.

10.0 Procedure

10.1 Sample Preparation

Remove the samples from the refrigerator, if refrigeration is required, and allow them to come to room temperature.

Soil samples must be homogenized prior to preparation in accordance with SOP SA-QA-015: *Compositing, Homogenization, and Segregation of Samples*.

10.1.1 Water Samples

10.1.1.1 Mix the sample thoroughly. Verify the sample pH as instructed in Section 8.1.3 and adjust as needed.

Note: If the pH is greater than 2 the sample must be held for 24 hours after pH adjustment and the pH re-verified.

10.1.1.2 Add 50mL of sample to a labeled 100mL digestion vial. For dilutions and high level samples, add an aliquot of the sample to the vial and dilute to volume with reagent water.

10.1.1.3 Add 1.25mL HNO_3, 2.5mL H_2SO_4, and 7.5mL of $KMnO_4$ solution to each sample, mixing after each addition of reagent.

The purple color of $KMnO_4$ must persist for at least 15 minutes. If not, an additional 7.5mL of $KMnO_4$ solution to the sample and mix. Up to three 7.5mL aliquots of KMnO4 (total of 22.5mL additional) may be added to the sample. If additional KMnO4 is added to the sample(s), then the same amount must be added to the MB also.

If the color does not persist after the additional 22.5mL of $KMnO_4$ is added, stop the digestion and start over with a smaller aliquot of sample.

Note: If a sample requires additional $KMnO_4$ solution to be added, then an NCM must be initiated to denote this situation.

10.1.1.4 Add 4mL of potassium persulfate to each sample, cap, shake well, **loosen cap**, and place the samples in a water bath or block digestion apparatus at 95 ± 3°C for at least 2 hours.

NOTE: To verify temperature of the hotblock a digestion tube filled with DI water must be placed at random locations across each block used for digestion. This position must be changed daily. A single thermometer is transferred from block to block and a minimum of 10 minutes allowed for the thermometer to equilibrate before taking the reading. This temperature reading, uncorrected and corrected, is then recorded in the batch information.

10.1.1.5 Remove the samples and allow them to cool to room temp. Add 3mL of sodium chloride-hydroxylamine sulfate solution to each bottle to neutralize excess $KMnO_4$.

10.1.1.6 Adjust the final volume to 75mL with reagent water.

If more than 15mL of $KMnO_4$ was added to the sample (Section 10.1.1.3), a dilution factor must be applied to the sample. Calculate the dilution factor (DF) as:

DF = (75mL + KMnO4 added) / 75mL.

10.1.2 Soil Samples

10.1.2.1 Homogenize the sample thoroughly. Weigh between 0.50-0.60g wet weight of sample into a 100mL digestion vial.

If the sample is a non-soil solid or will potentially form particles that can become air-borne when the sample is broken up, homogenize the sample under the hood. Tare the digestion vessel, take it to the hood, and add the sample to the vessel. Adjust the weight to 0.50-0.60g, adding the sample to the vessel under the hood.

10.1.2.2 Add 5.0mL DI water and 10mL of 1:1 aqua regia. Heat for at least 2 minutes in a water bath or digestion block at 95°C± 3°C.

10.1.2.3 Allow the samples to cool to room temperature.

10.1.2.4 Add 20mL DI water and 15mL $KMnO_4$ solution to sample, cap, and shake well.

The purple color of $KMnO_4$ must persist for at least 15 minutes. If not, an additional 7.5mL of $KMnO_4$ solution to the sample and mix. Up to two 7.5mL aliquots of $KMnO_4$ (total of 15mL additional) may be added to the sample. If additional KMnO4 is added to the sample(s), then the same amount must be added to the MB also.

If the color does not persist after the additional 15mL of $KMnO_4$ is added, stop the digestion and start over with a smaller aliquot of sample.

Note: If a sample requires additional KMnO4 solution to be added, then an NCM must be initiated to denote this situation.

10.1.2.5 **Loosen cap**, and place the samples in a water bath or block digestion apparatus at 95 ± 3°C for at least 30 minutes.

10.1.2.6 Allow the samples to cool to room temperature.

10.1.2.7 Add 6mL of sodium chloride-hydroxylamine sulfate solution to each bottle to neutralize excess $KMnO_4$. Dilute the sample to a final volume of 75mL.

10.2 Batch QC Sample Preparation

10.2.1 Water Samples

10.2.1.1 Method Blank – Add 50mL of reagent water to a 100mL disposable vial. Prepare in accordance with Section 10.1.1.

10.2.1.2 Laboratory Control Samples (LCS/LCSD) – Add 50mL of DI water to a 100-mL digestion vial. Add 0.25mL of the 500ug/L Hg Intermediate Standard to the vial and mix. Prepare in accordance with Section 10.1.1.

10.2.1.3 Matrix Spikes (MS/MSD) – Add 50mL of the sample selected for the batch matrix spike to a 100mL digestion vial. Add 0.10mL of the 500ug/L Hg Intermediate Standard to the sample. Prepare in accordance with Section 10.1.1.

Note: For EPA 245.1 Clean Water Act, EPA 7470A and EPA 7471B the matrix spike must be prepared in duplicate.

10.2.1.4 Low Level Laboratory Control Sample (LLCS) – Add 50mL of reagent water to a 100mL digestion vial. Add 0.02mL of the 500ug/L Hg Intermediate Standard to the sample and mix. Prepare in accordance with Section 10.1.1.

Note: The LLCS is only required for EPA 245.1 drinking water samples.

10.2.2 Soil Samples

10.2.2.1 Method Blank – Add 0.50-0.60g of blank matrix to a 100mL disposable vial. Prepare in accordance with Section 10.1.2 for soils.

10.2.2.2 Laboratory Control Samples (LCS/LCSD) – Add 0.50-0.60g of blank matrix to a 100mL disposable vial. Add 0.25mL of the 500ug/L Hg Intermediate Standard. Prepare in accordance with Section 10.1.2 for soil samples.

10.2.2.3 Matrix Spikes (MS/MSD) – Add 0.50-0.60g of the soil sample selected for the batch matrix spike to a 100mL disposable vial. Add 0.1mL of the 500ug/L Hg Intermediate Standard to the sample. Prepare in accordance with Section 10.1.2.

10.3 Analysis

10.3.1 Instrument Start-up and Operating Conditions

The instrument conditions listed in this SOP are provided for guidance purposes. The actual conditions used by the laboratory may be slightly different from those listed here and must be documented in the instrument maintenance log, data system, and/or run log.

Instrument maintenance must be performed in accordance with Attachment 4 of this SOP.

Before analysis begins, inspect the system (pump tubes, mixing coil, gas/liquid separator) to see if any parts need to be cleaned or replaced.

Inspect the drying tube. Clean or replace as needed with a pre-made drying tube from Leeman Labs that has been inspected for discoloration. Caution should be used if moisture is visible in the tubing that follows the drying tube.

Fill the rinse tank with rinse water.

If the lamp is not already on and warmed up, turn on the lamp. The lamp must warm up for a minimum of 2 hours.

If the lamp is already on and warmed up, make sure the platens have the appropriate tension and turn on the pump. Allow a minimum of 20 minutes of pump time for the pump tubes to break in each day.

Autosampler setup

Fill the standard tubes with the appropriate standards for the protocol being followed. (Refer to Section 10.3.4 for more information on method-specific analytical sequence and standards required.)

Fill the labeled sample test tubes with the samples and calibration verification standards in the proper order.

The method blank will be analyzed first. The LCS will follow immediately after the method blank. The samples, matrix spikes, and duplicates will then follow with a maximum of 10 analyses between CCVs/CCBs.

Enter the sample/QC IDs into the autosampler table giving each rack a unique name.

Load the rack(s) onto the autosampler.

10.3.2 Initial and Continuing Calibration

Calibrate the instrument using the standards and criteria described given in Section 9.2.1. Once the calibration has been established and verified with an ICV in accordance with Section 9.2.2, sample analysis may proceed.

Verify the calibration curve with a continuing calibration verification using the standards and criteria described given in Section 9.2.4.

Calibration of the Mercury Analyzer
Call up the required protocol. Open a new data folder.

Go to CALIBRATION, RESET, and reset the calibration for a new calibration.

Go to CALIBRATION, STANDARDS, and ensure that calibration standards are entered at the proper concentrations.

Analyze the standards, beginning with standard 1 (Blank), proceeding from lowest to highest concentration.

When all calibration standards have been analyzed, go to CALIBRATION, LINE CALIBRATION. If calibration is within acceptable limits, accept the linear calibration and print the calibration curve.

10.3.3 Sample Analysis

The digestate must be analyzed using the same volume as that used for the calibration standards. Samples known to be relatively clean should be analyzed first. Samples suspected of containing high concentrations should be analyzed last. Instrument blanks may be analyzed after suspected high concentration samples to allow the detector response to stabilize.

The default procedure is to include QC items (method blank, LCS, MS/MSD, and SD) in determining the maximum number of samples between CCVs/CCBs.

Sample Analysis
Go to AUTOSAMPLER, SETUP. Enter the Rack IDs and the cup numbers to be analyzed.

Carryover from high concentration samples usually affects only the next one to two samples in the sequence. The two samples following an off-scale sample that is greater than 10ug/L must be reanalyzed to verify the presence or absence of mercury and the quantitation of mercury. It is the responsibility of the analyst to clearly demonstrate that all mercury results are accurate and free from carry-over contamination.

10.3.4 Example Analytical Sequence

An example analytical sequence is listed below.

Analytical Sequence for samples immediately following an initial calibration:

Description	Comments
Blank	
Initial Calibration	
ICV	Second Source
ICB	
RL Standard	Required for EPA 245.1 (Not a requirement for EPA 7470A and EPA 7471B if calibrated to RL)
Samples & Batch QC Items	Up to 9 analyses, including QC.
CCV	
CCB	
Samples & Batch QC Items	Up to 10 analyses, including QC.
CCV	
CCB	

Analytical Sequence for samples not immediately following an initial calibration:

Description	Comments
CCV	
CCB	
Samples & Batch QC Items	Up to 10 analyses, including QC.
CCV	
CCB	
Samples & Batch QC Items	Up to 10 analyses, including QC.
CCV	
CCB	

11.0 Calculations / Data Reduction

11.1 Data Reduction

Data must be evaluated in accordance with SOP SA-QA-002: *Data Generation and Review*. See Section 9.2.9 for guidance on the evaluation of MS/MSD.

11.1.1 Dilutions

If the concentration of a sample is above the calibration range of the mercury analyzer, the sample digestate must be diluted and reanalyzed. The amount of digestate needed to prepare the desired dilution is determined from the following equation:

$$V_{digest} = \frac{V_{fv}}{DF}$$

Where:

V_{digest} = volume of sample digestate used to make the dilution
V_{fv} = final volume of diluted sample
DF = dilution factor

Note: Samples should be diluted with digested blank solution.

Note: This calculation assumes all applicable unit correction factors are applied.

The dilution factor is calculated as follows:

$$DF = \frac{V_{fv}}{V_{digest}}$$

Where:

V_{digest} = volume of sample digestate used to make the dilution
V_{fv} = final volume of diluted sample
DF = dilution factor

Note: This calculation assumes all applicable unit correction factors are applied.

If a sample exceeds the calibration range of the instrument by more than a factor of 10 (i.e., if the final, calculated result is greater than 50ug/L Hg at the instrument) the samples should be re-digested and reanalyzed with a smaller amount. This is a good check for possible positive bias of the sample by incomplete digestion of organic compounds. Initial weights or volumes of <0.2g or <1.0mL should be avoided, if possible, so that a representative sample can be achieved. If, due to the level of mercury in the samples, greater dilutions are required, consult with the Department Manager for further instructions.

11.1.2 Historical Data

Many of the laboratory's clients submit samples for repeat monitoring purposes. Prior to analysis, verify the TALS Worksheet Notes and/or use the TALS Historical Data Tracker feature to determine if historical data is available for review.

11.1.3 Chemical Relationships

When available, the following chemical relationships must be evaluated for each sample. If these relationships are not met, the Department Supervisor must be contacted immediately.

- Total Results are ≥ Dissolved results (e.g. metals)

11.1.4 Drinking Water Compliance Evaluation

Public water suppliers (PWS) are governed by EPA-specified Maximum Contaminant Levels (MCL) above which indicates noncompliance. The MCL associated with this procedure is 0.002mg/L.

11.2 Calculations

11.2.1 The calculations associated with batch QC determinations are given in SOP SA-QA-017. Applicable calculations include accuracy (% recovery) and precision (%RPD). Evaluate MS/MSD results using the guidance in Section 9.2.9.

11.2.2 The calculations associated with initial and continuing calibrations and are given in SOP SA-QA-016. Applicable calculations include determination for: calibration factor, standard deviation, relative standard deviation, relative response factor, and relative standard deviation.

11.2.3 The calculation to determine final concentration is given as follows:

Regression Curve:

$$FinalConcentration = CONC_{Sample} \otimes \frac{F}{I \times dw} \otimes D$$

Where:

$CONC_{Sample}$= Concentration of the sample
F = Final volume/weight
I = Initial volume/weight
dw = % Solids decimal equivalent
D = Dilution factor

Note: All dry weight corrections are performed automatically in TALS.

Note: This calculation assumes all applicable unit correction factors are applied.

12.0 Method Performance

12.1 Reporting Limit Verification (RLV)

At a minimum, RLVs must be performed initially upon method set-up in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits*.

For analytes and methods certified by DOD ELAP, RLVs must also be performed quarterly thereafter. For all other analytes and methods, RLVs must also be performed annually thereafter. Exceptions may be made for project-specific non-routine analytes.

12.2 Method Detection Limit (MDL) Study

The MDL is the lowest concentration that can be detected for a given analytical method and sample matrix with 99% confidence that the analyte is present. MDLs reflect a calculated (statistical) value determined under ideal laboratory conditions in a clean matrix and may not be achievable in all environmental matrices. The current MDLs associated with this procedure are given in the Method Limit Group (MLG) in TALS.

At a minimum, MDL Studies must be performed initially upon method set-up in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits*.

Note: MDL Studies are not required for non-routine analytes provided results are not reported below the RL (i.e., MDL equals RL in TALS).

12.3 Method Detection Limit Verification (MDLV)

At a minimum, MDLVs must be performed initially upon method set-up in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits*.

For analytes and methods certified by DOD ELAP, MDLVs must also be performed quarterly thereafter. For all other analytes and methods, MDLVs must also be performed annually thereafter.

Note: MDLVs are not required for non-routine analytes provided results are not reported below the RL (i.e., MDL equals RL in TALS).

12.4 Determination of the Instrument Detection Limit (IDL)

The instrument detection limit (IDL) is the concentration of analyte that can be statistically distinguished from the background noise of the instrument. The IDL limit must be determined annually, at a minimum, for each analyte in accordance with SOP SA-QA-007: *Determination and Verification of Detection and Reporting Limits (RLs, MDLs, and IDLs)*.

The IDL is defined as three times the average of the standard deviation of seven replicate analyses of the IDL solution performed over three non-consecutive days. The IDL may be elevated above the background noise (blank levels). The current IDL associated with this procedure is given in the Equipment Limit Group (ELG) in TALS.

12.5 QC Limit Generation, Control Charting, and Trend Analysis

The control limits for the batch QC items (LCS, MS/MSD, Analytical Spike) for this procedure are specified in the reference method and cannot be broadened; therefore, the laboratory defaults to the method-defined limits and does not utilize in-house or laboratory-derived limits for the evaluation of batch QC items.

Although the laboratory must default to the method-defined QC limits, control charting is a useful tool and is performed to assess analyte recoveries over time to evaluate trends. Control charting must be performed periodically (at a minimum annually) in accordance with SOP SA-QA-017: *Evaluation of Batch QC Data.*

12.6 Demonstrations of Capability

Initial and continuing demonstration of capability must be performed in accordance with SOP SA-QA-006*: Training Procedures.*

Prior to performing this procedure unsupervised, each new analyst who performs this analysis must demonstrate proficiency per method/analyte combination by successful completion of an initial demonstration of capability. The IDOC is performed by the analysis of 4 consecutive LCSs that meet the method criteria for accuracy and precision. The IDOC must be documented and routed to the QA Department for filing.

Annual continuing demonstrations of capability (CDOCs) are also required per analyst per method/analyte combination. The CDOC requirement may be met by the consecutive analysis of four LCS all in the same batch, by the analysis of four LCS analyzed in four consecutive batches (in different batches on different days), via acceptable results on a PT study, or analysis of client samples with statistically indistinguishable results when compared to another certified analyst. The CDOC must be documented and routed to the QA Department for filing.

12.7 Training Requirements

All training must be performed and documented in accordance with SOP SA-QA-006: *Training Procedures*.

Note: The SOPs listed in the Reference/Cross-Reference Section are applicable to this procedure. All employees performing this procedure must also be trained on these SOPs.

13.0 Pollution Control

It is Eurofins TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (e.g., examining recycling options, ordering chemicals based on quantity needed, preparing reagents based on anticipated usage and reagent stability, etc.). Employees must abide by the policies in Section 13 of the Environmental Health and Safety Manual and the Savannah Addendum to the EHSM.

This procedure has been evaluated for opportunities to minimize the waste generated. Where reasonably feasible, pollution control procedures have been incorporated.

14.0 Waste Management

Waste management practices must be conducted consistent with all applicable federal, state, and local rules and regulations. All waste (i.e., excess reagents, samples, and method process wastes) must be disposed of in accordance with Section 9 of the Eurofins TestAmerica Savannah Addendum to the EHSM. Waste description rules and land disposal restrictions must be followed.

14.1 Waste Streams Produced by the Method

The following waste streams are produced when this method is carried out:

- Excess aqueous samples – Dispose according to characterization on the sample disposal sheets. Neutralize non-hazardous samples before disposal into drain/sewer. Transfer hazardous samples (identified on disposal sheets) to the waste department for disposal.
- Excess soil and solid samples –Transfer RCRA and non-hazardous samples to the yard box for disposal vis incineration. If samples are classified as PCB or Foreign-soils the samples are transferred to the waste coordinator for drumming.
- Acidic sample digestions – Neutralize before disposal into drain/sewer system.
- Excess oil samples – Transfer to waste department for storage/disposal.

14.2 Waste Disposal

The table below summarizes the disposal process:

Material	Treatment	Destination
Aqueous Samples (Non-Haz)	Neutralization	Sink
Aqueous Samples (Haz)	Neutralization	RCRA Water Drum
Solid Samples (Non-Haz)	None	Yard Box
Solid Samples (Haz)	None	Yard Box
Standards	Neutralization	RCRA Water Drum
Nitric Acid	Neutralization	Sink
Sulfuric Acid	Neutralization	Sink
Hydrochloric Acid	Neutralization	Sink
Hydroxyl amine	None	Sink
Sodium chloride	None	Sink
Hydroxyl amine-sodium	React with KMnO4 until	RCRA Water Drum

chloride solution	KMnO4 is colorless	
Stannous chloride	None	RCRA Water Drum
Potassium permanganate	None	Lab pack
5% Potassium permanganate	React with hydroxylamine-sodium chloride until KMnO4 is colorless	RCRA Water
Potassium persulfate	None	Sink

16.0 Method Modifications

16.1 Incorporation of Non-Routine Matrices

This procedure may be modified to analyze other matrices (e.g., waste (oil), wipe, tissue, and TCLP/SPLP leachate samples) upon client request. This will need to be arranged by the Project Manager at the initiation of the project.

Waste (oil), wipe, and tissue matrices are non-routine, and the laboratory is not currently NELAC certified for these matrices. The laboratory uses its routine soil RLs (converted for initial and final volumes, etc.) and soil QC limits to evaluate wipe, waste, and tissue samples. Soil DOCs can be used to satisfy analyst demonstrations of capability for these types of non-routine matrices. Teflon chips or blank sand are used as the blank matrix for tissues unless a "true" tissue matrix is required by the project. The laboratory uses its routine soil RLs (converted for initial and final volumes, etc.) and soil QC limits to evaluate TCLP/SPLP leachate samples. Water DOCs can be used to satisfy analyst demonstrations of capability for TCLP/SPLP matrices.

16.1.1 Collection and Handling Procedures for Non-Routine Matrices

Waste (oil) samples are collected in 4oz plastic soil containers. Waste (oil) samples must be iced at the time of collection and maintained at 4°C (less than 6°C but not frozen) until the time of digestion. Waste (oil) samples must be digested and analyzed within 28 days of collection. Waste (oil) digestates are stored at room temperature until the time of analysis.

Wipe samples are routinely collected in 40mL VOA vials containing acetic acid in water, pH 4.93 +/- 0.05. Wipe samples must be iced at the time of collection and maintained at 4°C (less than 6°C but not frozen) until the time of digestion. Wipe samples must be digested and analyzed within 28 days of collection. Wipe digestates are stored at room temperature until the time of analysis. Refer to the Work Instruction on *Wipe Tests: Sampling and Analysis* for additional information on wipe procedures.

Tissue samples are routinely collected in plastic containers with the size dependent upon the type of tissue being collected. Plastic jars or plastic baggies can be used. Upon receipt, tissue samples must be placed in the freezer at -10° to -20°C if extraction/digestion cannot be completed that day. Per the EPA Region 4 guidance document used for tissue analyses, tissue samples can be stored frozen for up to 6 months, and must be digested and analyzed within 28 days of thawing.

For TCLP and SPLP samples, once the TCLP/SPLP extraction procedure has been performed, the leachate is transferred to a plastic container and refrigerated at 4°C (less than 6°C with no frozen samples). TCLP/SPLP leachates must be stored at 4°C (less than 6°C with no frozen samples) until the time of preparation and/or analysis. The leachate sample must be digested and analyzed within 28 days of completion of the TCLP/SPLP extraction.

16.1.2 Preparation and Analytical Procedures for Non-Routine Matrices

16.1.2.1 Waste (oil) samples are prepared in the same manner as routine soil samples, as outlined in Section 10.1 of this SOP. Waste (oil) QC samples are prepared in the same manner as routine soil samples, as outlined in Section 10.2 of this SOP.

16.1.2.2 Tissue samples are calculated on an "as is" basis and are prepared as outlined below. Tissue QC samples are prepared in the same manner as routine soil QC as outlined in Section 10.2 of this SOP.

Weigh between 1.0g and 1.2g of the sample and place into a 100mL disposable vial. Add 2mL H_2SO_4 and 0.5mL HNO_3 to each sample and digest in the waterbath or heating block for at least 30 minutes at 80°C +/- 3ºC or until the tissue is completely dissolved.

After samples are cooled, add 7.5mL of $KMnO_4$ (more $KMnO_4$ may be added if required), 4mL potassium persulfate solution, 25mL DI water and put samples back into water bath for an additional at least 90 minutes at 30°C +/- 3ºC. Be sure the purple color of $KMnO_4$ persists for at least 15 minutes prior to placing samples in the water bath or block digestion apparatus. If not, add 7.5mL of $KMnO_4$ solution up to three additional times.

Remove the samples and allow them to cool. Add 3mL of sodium chloride-hydroxylamine sulfate solution to each bottle to neutralize excess $KMnO_4$. Add 26mL DI water and shake well. This should give a final volume of 68mL.

Note: If additional volume(s) of $KMnO_4$ were added, compensate for the addition(s) by adding less DI water so that the final volume will remain constant.

16.1.2.3 Wipe samples are prepared as outlined in the Work Instruction, *Wipe Tests: Sampling and Analysis* (FQA088).

16.1.2.4 Waste (oil), tissue, and wipe samples are analyzed in the same manner as routine matrices as outlined in Section 10.3.

16.2 Other Considerations

16.2.1 The EPA Manual for the Certification of Laboratories Analyzing Drinking Water requires a LFB at the MRL to be performed each day. The laboratory meets this requirement by preparing an LCS at the RL in each EPA 245.1 batch of drinking water samples. The EPA DW Manual does not specify criteria for the low-level LCS (LLCS). The laboratory requires detection of this LLCS to be acceptable.

16.2.2 Calibration standards are assigned a hold time of 28 days and may be used to quantify samples prepped on the same day as the ICAL in cases where re-analysis is required.

16.2.3 The referenced liquid preparation methods call for an initial volume of 100mL of sample. The reference methods utilize BOD bottles that required 100mL of sample to reach the required detection limit. The newer instrumentation utilized by the laboratory requires less than 10mL of the final digestion for analysis. Therefore, this SOP utilizes a 50mL initial volume and the reagents added for digestion are lowered proportionately.

16.2.4 EPA 245.1 specifies a 100mL initial volume but allows for reduced volumes as long as the reagent ratios and quality control are met. The laboratory uses 50mL as its default initial volume, and reagent ratios have been adjusted accordingly. All method detection limits, demonstrations of capability, and PTs have been performed in this same manner.

16.2.5 EPA 245.1 specifies the use of stannous chloride/sulfuric acid suspension used to reduce mercury to elemental mercury. EPA 7470A and EPA 7471B specify stannous sulfate to be used to reduce elemental mercury to mercury; however, these methods also state stannous chloride dissolved in hydrochloric acid can be used as an option. In accordance with the instrument manufacturer's recommendations, the laboratory uses stannous chloride dissolved in hydrochloric acid as the stannous chloride/sulfuric acid suspension tend to clog the instrument's lines. All method detection limits, demonstrations of capability, and PTs have been performed in this same manner.

16.2.6 EPA 245.1 specifies that a Method Detection Limit (MDL) study to be performed annually and when a new analyst begins. The laboratory performs an MDL study initially, with MDL Verifications performed quarterly, and when a significant change is made to the equipment. The laboratory does not use analyst-specific MDLs; therefore, new analysts are required only to perform an initial demonstration of capability (IDOC) as described in Section 12.4.

16.2.7 EPA 245.1 specifies control criteria for the method blank as >10% the analyte concentration in the sample or 2.2 times the MDL, whichever is greater. The laboratory requires the method blank to be <1/2RL. The RL for this procedure is routinely within a factor of within ~3-5x the MDL; therefore, the 1/2RL criteria used for the method blank satisfies the method requirement.

16.2.8 EPA 245.1 requires a Linear Dynamic Range (LDR) study to be performed initially, with an LDR verification performed annually thereafter. An initial LDR study is performed in accordance with method requirements, and a re-evaluation of the calibration curve as samples is performed to satisfy the annual verification requirement. The laboratory dilutes all samples with concentrations above the high point of the calibration curve to bring them within the linear calibration range of the instrument.

16.2.9 EPA 7470A states non-aqueous samples must be analyzed as soon as possible. EPA 7471B states non-aqueous samples must be analyzed as soon as possible but should be held no longer than 28 days. Therefore, the laboratory defaults to a 28-day holding time for these methods.

16.2.10 EPA 245.1 does not contain a method-defined batch precision requirement. The laboratory's default QC items incorporate an MSD to satisfy the Clean Water Act requirements and those clients who batch require precision to be reported. Additionally, if insufficient sample volume is provided to perform the MS/MSD, the LCS is routinely prepared in duplicate (i.e., LCS/LCSD).

16.2.10 EPA 7471B requires the use of aqua regia prepared at a specific molarity. Due to safety concerns involving the use of such concentrated acid, the laboratory uses a more dilute solution than what is prescribed in the method.

16.2.11 EPA 245.1 includes the parenthetical phrase "without heating" in reference to preparation of calibration standards. The laboratory does not interpret this as an outright prohibition against the practice and believes it is acceptable to digest calibration standards, as is done for many other mercury methods. All method detection limits, demonstrations of capability, and PTs have been performed in this same manner.

Attachment 1:
SOP Summary

Sample Preparation and Analysis Summary

This procedure is based on the absorption of characteristic radiation at 253.7nm by mercury vapor. After digestion, to convert all forms of mercury to the same oxidation state, the mercury ions are reduced to mercury by the addition of stannous chloride and aerated from solution after passing through a mixing coil. The mixture passes through a gas/liquid separator and through a drying tube. The vapor is passed through a flow cell positioned in the light path of an atomic absorption spectrophotometer. Mercury concentration is measured as a function of absorbance.

Analytical Sequence

Analytical Sequence for samples immediately following an initial calibration:

Description	Comments
Blank	
Initial Calibration	
ICV	Second Source
ICB	
RL Standard	Required for EPA 245.1 and SM4110B (Not a requirement for EPA 7470A and EPA 7471B if calibrated to RL)
